# Using internal CPS data to reevaluate trends in labor-earnings gaps 

The Current Population Survey provides data that are used to compare gaps in the labor earnings of women and men, people of different races, and people of different levels of education; this article presents a data series that uses cell means and more accurately measures gaps and trends in earnings than do other publicly available series

Richard V. Burkhauser and Jeff Larrimore

The results and conclusions presented in this article are those of the authors and do not necessarily reflect the views of the U. S. Census Bureau. This article has been screened to ensure that no confidential data are disclosed.

Richard V. Burkhauser is a professor in the Department of Policy Analysis and Management at Cornell University. Jeff Larrimore is a Ph.D. candidate in the Department of Economics at Cornell University. Email: rvb1@cornell.edu, jhl42@cornell.edu

The Current Population Survey (CPS) is a large, nationally representative sample of households collected each month since 1942 by the U.S. Census Bureau. ${ }^{1}$ This article focuses on data from the surveys conducted in March because the March survey includes an extensive income questionnaire. The data that are publicly available from the CPS are the primary tool used to investigate yearly trends in United States average labor earnings and their distribution. However, to protect the confidentiality of its respondents, the Census Bureau topcodes the highest values from each source of income that it collects when it reports the income in the public-use CPS data. Topcoding is the replacement of a datum representing part or all of a person's true income with a lower value. One of the challenges that topcoding presents for those using the public-use data to examine labor-earnings levels and trends is that the topcodes vary over time, which leads to artificial increases or decreases in earnings (when the term "earnings" appears alone in this article, it still refers to "labor earnings") at the top of the earnings distribution as different fractions of the population are subject to topcoding each year. ${ }^{2}$ Although the public-use data are used extensively to measure the earnings
gaps between men and women and Blacks and Whites, ${ }^{3}$ until now little was known about how topcoding affects comparisons of labor earnings across these subsets of the population. ${ }^{4}$
This article finds that gaps between the earnings of men and women, Blacks and Whites, and people of various education levels are all sensitive to topcoding. Ratios of these earnings as well as trends in the gaps and ratios also are sensitive to topcoding. The article arrives at these findings by analyzing 1975-2007 CPS data and comparing the values of gaps and ratios obtained using the public-use CPS data with values found using the internal CPS data.
This article presents an extended cell mean series that will be explained in more detail in a later section. The earnings gaps calculated using the extended cell mean series in conjunction with public-use CPS data are found to closely approximate those obtained with the Census Bureau's internal CPS data. Additionally, this article finds that women, Blacks, and the less-educated are relatively worse off compared with men, Whites, and the more-educated, respectively, than previously reported using the public-use CPS data. Although the trends for all of the aforementioned earnings gaps are sensitive
to topcoding, the impact that attempting to correct for topcoding has on trends differs by year. ${ }^{5}$

## Calculating earnings gaps

To calculate gaps in earnings between men and women, between Blacks and Whites, and among people of various levels of education, this article examines the annual labor earnings from wages and salaries, self-employment, and farm earnings of full-time, full-year workers in the CPS. ${ }^{6}$ Prior to 1987 these "earnings sources" were reported as three separate values. Since then a fourth source-primary labor earnings (regardless of source) - has been added. The earnings sources and their names in the public and internal CPS data files are listed in table A-1 of the appendix. Much of the previous work exploring earnings gaps between men and women, between or among races, and among people of various levels of education focuses solely on wage and salary earnings and excludes self-employment and farm earnings, primarily because of concerns about the accuracy of self-employment earnings in the CPS. However, as Theresa J. Devine demonstrates, earnings gap data are sensitive to the inclusion or exclusion of selfemployment earnings since the earnings gap between men and women is larger among full-time self-employed workers than among full-time wage earners. ${ }^{7}$ Because the aim is to compare groups of people on the basis of all their labor market earnings, farm and self-employment earnings must be included along with wages.
An additional detail to consider is whether to analyze annual earnings or to instead recalculate the statistics as weekly or hourly wages. For this article a choice has been made to use annual earnings. The results are similar no matter which of these three methods is used; however, since women tend to work fewer weeks per year, using a weekly or hourly measure does generate a slightly smaller earnings gap between men and women. ${ }^{8}$
Another question is how best to calculate group earnings when calculating earnings gaps. To limit the impact of outliers on the earnings gap between men and women, the Census Bureau uses median rather than mean earnings when reporting the earnings gap between men and women in its Income, Poverty, and Health Insurance Coverage in the United States series. ${ }^{9}$ The Census Bureau does not calculate earnings gaps between people of different races or levels of education in this report. The gap in median earnings between men and women that is presented by the Census Bureau is regularly reproduced in factsheets by policy institutes and has been widely used as background
information in the literature on the pay gap between men and women. ${ }^{10}$ However, using median earnings comes at the cost of focusing only on the midpoint of the earnings distribution. As a result of the use of median earnings, if women make substantial gains compared with men at either tail of the distribution, a simple comparison of the median over time will probably understate these gains. Additionally, since earnings distributions are positively skewed in all years, mean earnings give relatively more weight than median earnings to changes in the upper tail of the distribution. So for researchers interested in this portion of the distribution, the mean is better able to capture differences between groups and changes over time. Because this article focuses on the upper tail of the distribution, where most topcoding occurs, it evaluates mean earnings, which better reflect changes occurring throughout the entire earnings distribution and are better able to capture the impact of topcoding on earnings gaps.
Despite these differences in calculating earnings gaps, the general trends in earnings gaps in the literature have generally been consistent. Most previous literature has found that the earnings gap between men and women was largely unchanged for much of the $20^{\text {th }}$ Century. It was not until the 1980s that women made substantial gains. In the 1990s, however, these gains subsided and the gap remained stable for much of the decade. ${ }^{11}$
While the consensus among researchers is that the earnings gap between Blacks and Whites also has been shrinking, the timing of its decline differs greatly from the timing of the decline in the earnings gap between women and men. The earnings gap between Blacks and Whites declined rapidly from the mid-1960s until the middle of the 1970s before stagnating or increasing slightly through much of the 1980s. ${ }^{12}$ There is some disagreement on the direction of the earnings gap between Blacks and Whites during the 1990s, with David Card and John E. DiNardo finding the gap more or less constant and Kenneth Couch and Mary C.Daly and Chinhui Juhn reporting a decline. ${ }^{13}$ The next section of the article shows the sensitivity of such earnings trends to four methods of dealing with topcodes in the CPS data.

## Topcoding CPS data

To protect the confidentiality of respondents, the Census Bureau topcodes each source of income that respondents report in the public-use CPS data. The full list of laborearnings topcoding thresholds over time is presented in tables A-2 and A-3 of the appendix. In addition to
topcoding each income source in the March CPS, the Census Bureau topcodes earnings reported in CPSs from other months, such as the usual weekly earnings reported in the surveys filled out by outgoing rotation groups. ${ }^{14}$ The further topcoding prevents researchers from obtaining additional earnings information from other questions in the CPS. Because topcodes vary over time, they can affect both the sizes of earnings gaps and their trends over time.
Prior to 1995, the Census Bureau simply replaced the value for each source of an individual's income that was topcoded with the level of income at the threshold for topcoding. Starting with 1995 data, the Census Bureau instead began replacing the income figure with a cell mean-the mean value of all topcoded data from the source of income in question. For labor earnings, each cell contains earnings figures from workers who are all of the same sex and race and who all either work both full time and year round or do not. Because the Census Bureau has not provided cell means retroactively for years prior to 1995, using the public-use CPS data without taking this major change in reported earnings values into account results in a sizable increase in measured earnings in 1995 and beyond. Hence, while the use of cell means starting in 1995 causes the public-use CPS data to conform better to the internal CPS data, not taking the improvement in measurement into account will overestimate actual increases in labor earnings from any year before 1995 to 1995 or any year after. ${ }^{15}$
Topcoding also has important implications for measuring the relative labor earnings of subsamples of the population and measuring gaps in earnings among subsamples. For example, if the distributions of labor earnings of women and men were identical, individuals' earnings in both groups would be topcoded at the same rate. So, topcoding would reduce the mean earnings of both men and women by the same percentage, leaving intergroup inequality unchanged.
However, if individuals in the two groups have different probabilities of being topcoded or if the mean suppressed labor earnings of those who are topcoded differ between the two groups, topcoding will influence the earnings gap measure. Because a larger percentage of women than men are below the topcoding threshold, women are less likely to be topcoded; it can be expected that topcoding will artificially raise the ratio of women's mean earnings to men's mean earnings, because the women's observed mean earnings will be less artificially depressed from the topcodes than those of men and hence will be closer to their true mean. Similar results will occur even if the probability of topcoding is the same across both groups, provided that
the amount of suppressed earnings is higher for men than for women. The same holds for Blacks relative to Whites and those with less education relative to those with more education.

## Prevalence of topcoding

Table 1 shows, for the trough year of each business cycle since 1975, the percentages of various groups of full-time, full-year workers who have had earnings from at least one source topcoded in the public-use CPS data. ${ }^{16}$ The groups of people are organized by sex (men and women), race (Blacks and Whites), and level of education attained (less than a high school degree, a high school degree but no higher education, and education beyond high school). The three business cycles run from 1975 to 1982, from 1982 to 1992, and from 1993 to 2004. The method for selecting the starting points and endpoints of business cycles in this article has been chosen somewhat arbitrarily. Rather than define business cycles directly by changes in macroeconomic growth, this article uses troughs in income, which in general lag behind macroeconomic growth. Choosing slightly different trough years would not have a significant effect on this article's findings. Although it is not a trough year, 1992 is included in the table. As will be discussed in more detail later, Census Bureau data collection procedures were redesigned after 1992. This reduces the ability to compare 1992 data with 1993 data. So 1993 represents both the trough year of the 1993-2004 business cycle and the first year of the new procedures. Like 1992, the year 2007 is not a trough year, but it is included in the table because it is the most recent year for which data are available. The business cycles are measured from trough to trough.
As can be seen in table 1, although the percentage of people whose earnings are topcoded varies by sex, race, and level of education, the overall incidence of topcoding has increased greatly over the past 30 years for every group of workers in the table. For example, virtually no women or black full-time, full-year workers had topcoded labor earnings in 1975, but close to 1 percent of each group had topcoded earnings in 2007.
While topcoding has been rising among the earnings of men, women, Blacks, Whites, and people of all three levels of education, in any given year there are noticeable differences in topcoding rates among these groups. Because women's earnings are less likely to be topcoded than those of men, one expects to find a larger difference between men's observed labor earnings and their true mean labor earnings than one expects to find for women's observed

Table 1. Percentages of various groups of full-time, full-year workers whose labor earnings are topcoded, and ratios of selected percentages; by year, selected years,1975-2007

| Year | Women | Men | Ratio | Blacks | Whites | Ratio | Less than a high school degree | High school degree | Education beyond high school | Ratio | Ratio |

SOURCE: Authors' calculations made by use of public and internal CPS data.
and true earnings. Correcting for topcoding should show that the gap between women's and men's earnings is wider than previously reported. For the same reasons, one can expect that correcting for topcoding will show that the gap between the earnings of Blacks and those of Whites is wider than previously reported and that the gap between the earnings of people with a high school degree or less and the earnings of those in higher education groups also is wider than previously reported.
As can be seen in the table, topcoding ratios also have changed over time. In 2007, women were topcoded 33 percent as much as men, up from only 2 percent as much in 1975. In 2007, Blacks were topcoded 37 percent as much as Whites, compared with 1975 when no Blacks were topcoded. On the whole, from 1975 to 2007 the less-educated showed larger increases in topcoding than did the more-educated. Hence, trends in earnings gaps between the sexes, between Blacks and Whites, and among people of varying levels of education are expected to be affected by topcoding.

## Methods of managing topcoding problems

The issue of topcoding can be handled in various ways. A first approach-referred to for the purposes of this article as "Unadjusted Public Use"-is to simply ignore topcoding issues and use the unadjusted public-use CPS data as released by the Census Bureau. However, as discussed earlier, doing so will result in a series whose labor-earnings levels are suppressed prior to 1995, because of topcoding, and are much higher thereafter, primarily because of the Census Bureau's introduction of cell means in 1995. This shift to cell means in 1995 is further complicated by changes to
topcoding thresholds made by the Census Bureau at the same time. For instance, the topcode for primary earnings rose from $\$ 99,999$ to $\$ 150,000$, thus reducing the share of full-time male workers whose primary labor earnings were topcoded from 3.93 percent to 1.35 percent, but the use of cell means increases the average reported primary labor earnings of those men who were still topcoded to \$305,989.
A second approach-referred to as "No Cell Mean Public Use"-is to ignore the introduction of cell means into the public-use CPS data and to produce a labor-earnings series in which all topcoded values are assigned the value of the topcoding threshold, even those values which date from after the introduction of cell means in 1995. While this approach removes the large artificial jump in labor earnings due to the introduction of cell means in 1995, it does not address the problem of inconsistent changes in topcoding thresholds over time (such as the change in the primary labor earnings topcode from \$99,999 in 1994 to $\$ 150,000$ in 1995) or the variation in topcoding rates across groups within the U.S. population. ${ }^{17}$
A third approach, used by Richard V. Burkhauser, J. S. Butler, Shuaizhang Feng, and Andrew J. Houtenville for labor earnings and by Burkhauser, Couch, Houtenville, and Ludmila Rovba for household income, is to create a consistent topcode series-an approach referred to as "Consistent Topcode Public Use." ${ }^{18}$ For each earnings source, this series finds the year in which the topcoding threshold cuts most deeply into the source's earnings distribution and then for every other year applies whatever topcoding threshold cuts into the source's earnings distribution by the same percentage. This approach is preferable to both the Unadjusted Public Use
approach and the No Cell Mean Public Use approach in that it consistently measures a given percentage of the distribution of the earnings from the source in question in all years of the study. However, this consistency over time in topcoding rates comes at the cost of losing information by topcoding a larger fraction of the population in almost every year. In this article, which analyzes labor earnings for full-time, full-year workers, the Consistent Topcode Public use approach cuts into the data by anywhere from 2.5 to 3.8 percent. The public-use CPS data reflect a cut (due to topcoding) that ranges from 0.6 to 2.7 percent, depending on the year.
Just as the existence of topcoding in the public-use CPS data can distort gaps in earnings and trends in earnings inequality across groups, increasing the fraction of the population that is topcoded can exacerbate the problem. Because more individuals are topcoded with the Consistent Topcode Public Use approach than they are in the public data, the observed mean labor earnings of each group within the population will be lower. But, because most of the people who are captured by the reduction in the topcodes are men, white, or more educated, using this approach will reduce the mean earnings of these groups more than it will reduce the mean labor earnings of women, Blacks or the less-educated. Hence, the Consistent Topcode Public Use method will consistently overestimate the mean earnings of workers with the former set of characteristics relative to workers with the latter characteristics by disproportionately excluding the top part of the labor-earnings distribution.
Given the limitations of consistent topcoding in providing a consistent comparison of the economic wellbeing of subpopulations, a new method for controlling for topcoding in the public-use CPS data is needed. As mentioned earlier, the Census Bureau began using cell means in 1995. Cell means from before 1995 are what is necessary to create an unbroken series that is based on cell means. Jeff Larrimore, Burkhauser, Feng, and Laura Zayatz have employed approximately the same method the Census Bureau used to create its cell means from 1995 onward in order to generate cell means that date back to 1975. ${ }^{19}$ With these cell means, it is possible to create an unbroken cell-means-based data series that can be used with the public-use CPS data. The earnings distributions in this series better match those found in the internal CPS data for each of the population subgroups examined.
To create the extended cell mean series for each source of labor earnings, the population is divided by sex, race, and employment status, the same categories the Census Bureau uses to produce its cell means. The topcoded earnings value
is then replaced with the weighted mean earnings-from the source of earnings in question-of all individuals with the same set of demographic characteristics for whom the source of earnings in question is topcoded in the publicuse CPS data. To protect the confidentiality of respondents' identities, when fewer than 5 individuals are topcoded from an earnings source, those individuals' earnings are combined with the earnings of individuals from a similar earnings source in order to obtain a cell size of 5 or more and generate a cell mean. (This procedure for preserving confidentiality is the same as that used by the Census Bureau.)
Although this new approach for correcting the effects of topcoding-an approach referred to as "Cell Mean Public Use"-has significant advantages over consistent topcoding because it allows one to better understand changes at the high end of the earnings distribution, it still does not capture the full distribution. In addition to topcoding income in the public-use CPS data, the Census Bureau censors high-income values for each source of income in the internal CPS data. The full list of points beyond which labor earnings are not released internally-termed "censoring points" in this article-is reported in tables A-2 and A-3 of the appendix. Since the internal CPS data are censored, values at the very top of the distribution for each source of income cannot be observed in these data. ${ }^{20}$ This poses a potential problem when creating a cell mean series for the public-use CPS data from the internal CPS data, because at best the trends in the series will match those found in the internal data from which the cell means are created. If changes in the censoring points in the internal CPS data affect earnings gaps, ratios, or trends in the Internal series, the same gaps, ratios, and trends will be affected in the Cell Mean Public Use Series.
While this is a limitation of the cell mean series in measuring the "true" trends in labor earnings, the problem is not as serious as it could be because the censoring points in the internal CPS data are much higher than the topcodes in the public-use CPS data. As a result, the fraction of individuals who are affected by censoring points is lower than the fraction affected by the public-use CPS topcodes. Thus, although some censoring does occur in the internal CPS data, the results calculated using the extended cell mean series with the public-use CPS data (that is, using the Cell Mean Public Use approach) are much closer to the results that would be obtained using data that consistently captures the full earnings distribution.
Additionally, the censoring points tend to be more stable than their counterparts used for the public-use CPS
data, the topcoding thresholds. Since the Census Bureau switched from reporting three sources of labor earnings to four sources in 1987, the only years in which changes were made to censoring points were 1992 and 1993.
Problems with data from the years 1992 and 1993 are not limited to the internal data. In 1993 the Census Bureau also implemented a substantial redesign of its collection procedures, a redesign that included the implementation of computer-assisted data collection. ${ }^{21}$ The change in procedures increased the ability of the Census Bureau to observe earnings near the top of the distribution; since those high earnings are observed in the internal data but are topcoded in the public-use data, the use of internal data exacerbates the observed break in the series. Therefore, although the use of cell means with publicuse CPS data allows for consistent trends before and after these years-trends that closely match the internal CPS data-researchers should take caution when using the cell mean series, or any CPS-based earnings series, to compare the year 1992 or any year before with the year 1993 or any year after.

## Accuracy in capturing mean labor earnings

As was explained in the previous section, men's and women's mean labor earnings were calculated using four methods of dealing with topcoding. Each cell in panel 1 of table 2 is the ratio of a datum from one of the four series to its corresponding figure from the internal CPS data. There are separate columns for men and women. A ratio of 1.000 indicates that the method perfectly captures the mean earnings observed in the Internal data series. The lower the ratio, the more earnings are missed as a result of topcoding.
As can be seen when looking at the data for 2007, because of the cell means provided by the Census Bureau, the mean earnings of full-time, full-year male and female workers captured in the Unadjusted Public Use data since 1995 are very close to the mean earnings in the Internal data series. So, for people only interested in years since 1995 (the year cell means were first provided by the Census Bureau), the men's and women's earnings statistics in the Unadjusted Public Use data and the Cell Mean Public Use data come very close to matching the corresponding statistics in the Internal series.
But for those also interested in years prior to 1995, the Unadjusted Public Use data series is flawed because it does not provide cell means for earnings that are above the threshold for topcoding. Hence, its mean values are smaller for both men's and women's earnings. In contrast,
the Cell Mean Public Use data provide yearly means very close to those from the Internal series for both men and women in all years back to 1975 , coming within 0.2 percent of the internal mean values for both men and women in each of the trough years.
Unlike the Unadjusted Public Use and Cell Mean Public Use series, the No Cell Mean Public Use and the Consistent Topcode Public Use series understate the mean earnings of both men and women in all years. Additionally, the amount by which earnings are understated through the use of these series has grown over time. For example, the mean earnings that are calculated using the Consistent Topcode Public Use series understate the results in the Internal series by 4.9 percent for men and 0.2 percent for women in 1975. By 2007 the gap between the Consistent Topcode Public Use series and Internal series rises to 9 percent for men's earnings and 4 percent for women's earnings.
As is seen in panels 2 and 3 of table 2 , the methods for managing topcoding have effects on the calculations of mean earnings of black and white workers and of workers with different levels of education that are similar to the methods' effects on the calculation of men's and women's earnings. Mean earnings computed using the Cell Mean Public Use series in all years or the Unadjusted Public Use series after 1995 closely match the mean earnings calculated using the Internal series. Use of the Consistent Topcode Public Use or the No Cell Mean Public Use series understates mean earnings (in relation to the Internal series), doing so more for white than for black workers and more for more highly educated workers than for less-educated workers.

## Accuracy in capturing earnings gaps

Having shown that mean earnings of men, women, Blacks, Whites, and people of three levels of education are influenced by the height of topcoding thresholds, the article now focuses in this section on differences among the No Cell Mean Public Use, Consistent Topcode Public Use, Cell Mean Public Use, and Internal series in order to explain how topcoding affects earnings gaps. The Unadjusted Public Use series is excluded from further discussions because its data from prior to 1995 are identical to the No Cell Mean Public Use series and its data from 1995 onward are nearly identical to the Cell Mean Public Use series. In addition, the Unadjusted Public Use series has a clear artificial jump in 1995 that makes it inferior to either the No Cell Mean Public Use series or the Cell

Mean Public Use series alone.
The gap in earnings between women and men. Because the No Cell Mean Public Use and Consistent Topcode Public Use series consistently understate the labor earnings of both men and women, the true ratio of women's earnings to men's earnings could in principal be greater or less than the ratio in the Cell Mean Public Use and Internal series. But as tables 1 and 2 have shown, men are more likely than women to be topcoded, and the average man who is topcoded has a higher wage or salary than the average woman who is topcoded. One therefore expects the ratio of women's earnings to men's earnings to be higher in the No Cell Mean Public Use and Consistent Topcode Public Use series than in the Cell Mean Public Use and Internal series, especially in the years for which cell means were not calculated.
The expectation proves to be true, as can be seen in chart 1 , which compares the ratio of mean women's earnings to mean men's earnings as calculated using each of the four data series. In all years, the ratio of women's earnings to men's earnings is larger according to the No Cell Mean Public Use series than according to the Internal series. This
difference is relatively small in the first year of the sample, but grows over time. In 1975 it was under 1 percentage point-female workers earned 56.6 percent of what male workers earned according to the No Cell Mean Public Use series, and they earned 55.8 percent of what male workers earned according to the Internal series-in 1989 it was over 2 percent, and in 2007 it was 2.8 percent. Thus, using the public-use CPS data without cell means will cause researchers to overstate the decline in the earnings gap between men and women over these years.
This overstatement is even greater when the Consistent Topcode Public Use method is used, since this approach further suppresses values at the top of the earnings distribution and topcodes even more men's earnings relative to women's earnings. Using consistent topcoding overstates the ratio of women's earnings to men's mean earnings by 2.8 percentage points in 1975, and the overstatement rises to 4.0 percentage points by 2007. In contrast, as can also be seen in chart 1 , the Cell Mean Public Use series nicely approximates the women-to-men earnings ratios found using the internal CPS data.
The chart shows that the gap between the earnings ratio calculated using the No Cell Mean Public Use series and

Chart 1. Ratio of women's mean labor earnings to men's mean labor earnings, according to four data series, 1975-2007

Source: Authors' calculations made by use of public and internal CPS data.
that calculated using the Internal series widens over time. The same happens for the Consistent Topcode Public Use series relative to the Internal series. Because of the widening of the gaps between the ratio calculated using the Internal series and the ratios calculated using the other two series, it might be assumed that using either of the other two series will overstate the earnings gains made by female workers relative to male workers for each of the three business cycles occurring during the 19752004 period. However, it will be shown that this is not the case.
Panel 1 of table 3 shows the percentage change in the ratio of women's mean earnings to men's mean earnings over each of the three business cycles that have occurred since 1975. As was done previously, direct comparisons
across 1992-93 are excluded from the analysis because of the Census redesign.
When the years from 1975 to 2004 are grouped into the business cycles of 1975-82, 1982-92, and 1993-2004, one finds that in each of the three business cycles the percentage change calculated with the Cell Mean Public Use series closely matches that calculated with the Internal series. In contrast, both the Consistent Topcode Public Use and the No Cell Mean Public Use series understate the percentage change that occurred in the 1975-82 business cycle and, to a lesser extent, also understate the change that occurred during the 1993-2004 business cycle. However, for the 1982-92 business cycle, these two series overstate the relative earnings gains of women. Thus, while each of these two series slightly misstates the relative earnings gains of

women in all three business cycles, the direction of the misstatement is specific to the time period analyzed.

The gap in earnings between Blacks and Whites. Chart 2 shows the ratio of Blacks' mean earnings to Whites' mean earnings during the 1975-2007 period, according to the Internal series and each of the three methods of correcting for topcoding. Similar to the case of the ratio of women's mean earnings to men's mean earnings, using the No Cell Mean Public Use series overstates the relative earnings of black workers; the extent of this overstatement grows over time from 0.9 percentage points in 1975 to 2.9 percentage points in 2004 before falling back to 1.3 percentage points in 2007. In another parallel to the ratio of women's earnings to men's earnings, the Consistent Topcode Public Use series overstates the relative earnings of black workers by even more than the No Cell Mean Public Use series, as white workers are more likely to be near the top of the earnings distribution and thus have additional earnings suppressed by consistent topcoding. However, the earnings ratio calculated from year to year with the Cell Mean Public Use series again closely matches the ratio from the Internal series, and it is the best available method of replicating the earnings gap seen
in the Internal series.
Panel 2 of table 3 displays the percentage change in the ratio of Blacks' mean earnings to Whites' mean earnings for each of the three business cycles. For every business cycle, the relationships among trends in the ratios of Blacks' mean earnings to Whites' mean earnings are similar to the relationships among trends in the ratios of women's mean earnings to men's mean earnings. Again, the Cell Mean Public Use series closely matches the trends in the Internal series for all three business cycles. Additionally, one also can see that during the 1975-82 business cycle, the Consistent Topcode Public Use and No Cell Mean Public Use series both slightly understate the relative gain in earnings made by black workers, as compared with the Internal series. For the 1993-2004 business cycle, the Consistent Topcode Public Use and No Cell Mean Public Use series understate the relative decline in Blacks' earnings in relation to Whites' earnings. For the 198292 business cycle the No Cell Mean Public Use and the Consistent Topcode Public Use series slightly overstate the earnings gains made by black workers. As was the case regarding men's and women's earnings, although these two series slightly misstate the percentage change in the ratio of Blacks' mean earnings to Whites' mean earnings,

## Chart 2. Ratio of Blacks' mean labor earnings to White's mean labor earnings, according to four data series, 1975-2007

SOURCE: Authors' calculations made by use of public and internal CPS data.
the direction of this misstatement varies over the three business cycles.
It may not come as a surprise that the Cell Mean Public Use series is nearly able to replicate the results from the Internal series in generating comparisons of women with men and Blacks with Whites, since sex and race were two of the conditioning criteria used when generating the cell means for each earnings source. Thus, a natural question is whether the Cell Mean Public Use approach is as successful at replicating the Internal series for subsets of the population that do not match the conditioning criteria.

Education mean earnings gaps. Mean earnings were calculated for the three levels of education previously mentioned: no high school degree, a high school degree but no higher education, and education beyond high school. For the 1975-2007 period, chart 3 displays the ratio of the mean earnings of workers with a high school degree but no higher education to the mean earnings of those without a high school degree. Chart 4 shows the ratio of the mean earnings of workers with education beyond high school to those of workers with only a high school degree. Both the charts present their respective
ratios as calculated using data from the Internal series and each of the three methods of correcting for topcoding. In the creation of cells, level of education was not controlled for like sex and race were; therefore, the cells contain earnings figures from people of various levels of education. Nevertheless, as was seen with the earnings gaps between men and women and between Whites and Blacks, the "education earnings gaps" that are calculated using the Cell Mean Public Use series very closely match those calculated with the Internal series. Thus, it does not seem that the benefits of using cell means are confined to data calculated using the conditioning criteria of sex, race, and employment status.
Additionally, this article finds that the degree to which labor earnings are understated when one uses the No Cell Mean Public Use or Consistent Topcode Public Use series increases with education because those with education beyond high school are more likely to have higher labor earnings and thus are more likely to have earnings suppressed by topcoding. Among the lower two education groups, there actually are some years in which the workers without a high school degree have earnings suppressed at a slightly higher rate than those with a high school degree, which causes the ratio of the mean

earnings of the group with more education to the mean earnings of the group with less education to be higher in the No Cell Mean Public Use Series and the Consistent Topcode Public Use series than in the Internal series. In contrast, among the higher two education groups, in all years earnings are suppressed at a higher rate among those with some higher education than those with just a high school degree; therefore, not appropriately correcting for topcoding will lead to an understatement of the returns to higher education.
Panels 3 and 4 of table 3 present percentage changes in ratios of mean earnings for the business cycles of 197582, 1982-92, and 1993-2004, as calculated using data from the Internal series and the three other data series. The subject of panel 3 is the ratio of the mean earnings of workers with a high school degree but no higher education to the mean earnings of workers without a high school degree; the subject of panel 4 is the ratio of the mean earnings of workers with education beyond high school to those of workers with a high school degree but no higher education. Panels 3 and 4 take the same approach as panels 1 and 2 except that in panels 3 and 4 , the ratio is of the group with the higher earnings to the group with
the lower earnings. (The ratio is the other way around in panels 1 and 2).
In each of the first two business cycles, there is a similar pattern to that seen for the mean earnings ratios of women to men and Blacks to Whites: the percentage changes calculated using the Cell Mean Public Use series are quite similar to those calculated the Internal series. Considering all three business cycles, the No Cell Mean Public Use series and Consistent Topcode Public Use series are less accurate in capturing trends, but, as is the case in panels 1 and 2 , the direction of the misstatement is not systematic; the percentage change is understated in some years and overstated in others.
In contrast to the findings concerning the earnings ratios of women to men and Blacks to Whites, in panels 3 and 4 the trends in data calculated using the Cell Mean Public Use series do not closely match the trends in data calculated using the Internal series in all three business cycles. In the 1993-2004 period, the Cell Mean Public Use series somewhat overstates the relative increase in the earnings of workers with a high school diploma (but no higher education) in relation to the earnings of workers without a high school diploma. This misstatement of the
trend occurs primarily because the cells do not control for education, thereby causing variations in how closely cell means represent the individual components of the cells. Nonetheless, in calculating the relative earnings of the lower two education groups, the Cell Mean Public Use series still approximates the Internal series better than do the other series.
For the 1993-2004 period the Cell Mean Public Use series somewhat understates the relative increase in the earnings of workers with some higher education in relation to workers with a high school diploma but no further education. Upon closer inspection, however, it can be seen that this understatement results mainly from the choice of 1993 as the first year in the timespan in question. In 1993 the difference (of 0.026) between the Internal and the Cell Mean Public Use series values for the earnings gap between those with some higher education and those with only a high school diploma is at its second largest amount over the entire 1975-2007 period. When 1994 is used as the base year, the Cell Mean Public Use values are much closer to the Internal series values. Thus, it is not that the Cell Mean Public Use series is unable to capture the trends in the Internal series in recent years, but rather that it does a poor job when 1993 is the anchor year.

Topcoding is a well-documented problem for the CPS, but until recently, the only available strategy for mitigating the problem has been to place further restrictions on the data, either by using consistent topcoding or by discarding the cell means provided by the Census Bureau from 1995 onward. As a result, calculations have tended to understate true mean earnings in the United States. When comparing earnings across two groups within the population that are topcoded at different rates, all previously available topcode correction schemes may lead to a misstatement of the earnings gap between the groups.
The authors of this article were able to partially lift the constraints of topcoding by obtaining access to the internal CPS data files. Although these internal data also are topcoded, the topcoding thresholds (censoring points) are substantially higher and more stable over time than those in the public-use CPS data. The key to this article is the extension of the cell mean series provided by the Census Bureau. The extension of cell means back to 1975 allows researchers using the public-use CPS data to estimate the earnings of individuals above the topcode threshold. Using the Cell Mean Public Use series with the public-use CPS data makes it possible to closely match the results found using internal CPS values from 1975 to 2007. Although the Cell Mean Public Use series best approximates the earnings
statistics in the internal CPS data for groups based on race, sex, or employment status-because these characteristics are controlled for in the creation of cells-the cell mean series also is very useful for approximating the internal data for groups formed on the basis of other criteria, such as education level. Since the Cell Mean Public Use series is now available to the general public, researchers who are interested in exploring not just trends in earnings gaps and ratios but also more detailed questions about the underlying causes of gaps in pay can use the series to answer their questions with a precision similar to that obtained with access to the internal CPS files.
For this article, four data series were used to calculate earning gaps between women and men, between Blacks and Whites, and among people of three levels of education-all who worked full time year round. Using the Cell Mean Public Use series resulted in earnings gaps that, on the whole, were moderately larger than those calculated using the No Cell Mean Public Use series. According to the public-use data without cell means, in 2007 the mean earnings of women who worked full time year round were 75.1 percent of those of their male counterparts. The figure drops to 72.3 percent when topcoding is accounted for through the use of cell means. Similarly, in 2007 the mean earnings of Blacks were 74.0 percent of those of Whites without the use of cell means, compared with 72.6 percent with the use of cell means. The largest change, however, occurs for groups based on educational attainment. For the year 2007, the mean earnings of workers with some postsecondary education were 64 percent more than the mean earnings of those with only a high school degree as calculated with data from the Cell Mean Public Use series, compared with 57 percent as calculated using the No Cell Mean Public Use series. Thus, the returns to higher education are understated substantially if cell means are not used.
Sizes of individual earnings gaps and trends in earnings gaps both are sensitive to the choice of method of correcting for topcoding. Ignoring cell means and the earnings of individuals above the topcoding thresholds will distort the measured trends in earnings ratios between women and men, between Blacks and Whites, and among groups of different levels of education. However, unlike the case of earnings gaps, the direction of the distortion is not consistent and is sensitive to the years chosen for calculating the trends. Using public-use data without cell means will overstate relative changes in the earnings of women, Blacks, and the less-educated in some years but will understate relative changes in their earnings in other years.

## Notes

ACKNOWLEDGMENTS: Support for the research in this article came from the National Science Foundation and the National Institute for Disability and Rehabilitation Research. The authors thank Lisa Marie Dragoset, Ian Schmutte, Arnie Reznek, Laura Zayatz, the Cornell Census RDC Administrators, and all their U.S. Census Bureau colleagues who have helped with this project.
${ }^{1}$ Each year the U.S. Census Bureau uses March CPS data to calculate yearly average income and poverty rates, and it releases these rates to the public; see www.census.gov/prod/2008pubs/p60-235.pdf (visited July 27, 2009) for more details. The March CPS data that the Census Bureau uses in its calculations are not available, except under certain conditions, to researchers outside of the Census Bureau.

The topcoding thresholds used for internal data come from the authors' calculations, which were made by use of internal CPS data.

# New wherever-provided services and construction indexes for PPI 

A new set of wherever-provided services and construction price indexes expands the BLS products covering the services and construction sectors of the economy; these indexes combine prices from all industries producing a specific service or construction product into a single price index for that service or product

Jonathan C. Weinhagen and
Bonnie H. Murphy

Jonathan C. Weinhagen is an economist, and Bonnie H. Murphy is a supervisory economist, in the Office of Prices and Living Conditions, Bureau of Labor Statistics. E-mail: weinhagen.jonathan@bls. gov or murphy.bonnie@ bls.gov

Effective with the release of July data on August 18, 2009, the Bureau of Labor Statistics (BLS) introduced a new set of wherever-provided (that is, com-modity-based) services and construction price indexes. The new indexes measure price change for specific services and construction products, regardless of the provider's industry of origin.

## Background and definitions

Prior to the mid-1980s, the BLS published industry and commodity-based price indexes for only the goods sector of the economy (mining, manufacturing, agriculture, and utilities). Due to the rapid growth of the U.S. services sector, the BLS undertook an effort to expand its coverage to include services and construction price indexes. This effort resulted in the publication of the first BLS industry-based service price index, the PPI for rail transportation, in January 1985. Through the mid-1990s, the services expansion effort continued, with the development of price indexes for many industries in the transportation sector that had relatively straightforward pricing methodologies. Over the past two decades, expansion efforts have moved forward to include indexes for more complex industries in the information,
health care, real estate, professional services, administrative services, finance and insurance, and wholesale and retail trade sectors. Measuring price changes for industries in these sectors required the development of new, innovative pricing concepts, diverse sampling strategies, and unique data collection techniques. The BLS currently calculates and publishes price indexes representing approximately 77.4 percent of services ${ }^{1}$ and 28.6 percent of total nonresidential construction. ${ }^{2}$ Still, gaps in the coverage of services exist; for example, education services, computer systems design and related services, and scientific research and development services are not covered.

As the BLS has expanded its coverage to include both the services and construction sectors of the economy, the expansion effort has focused primarily on the development of industry-based price in-dexes-indexes that measure price change for the output of an industry, including its primary, secondary, and miscellaneous production. Primary production is considered the industry's main revenue-generating activity, whereas secondary and miscellaneous production encompasses additional activities from which the industry generates revenue. Secondary production is the production of nonprimary goods, while
miscellaneous production is the provision of nonprimary services. For instance, the primary output of the wired telecommunications industry (NAICS 517110) is telephone-line provision services, such as local services, toll services, and private-line services. Miscellaneous production of this industry would include wired telecommunications services.

In contrast to industry-based indexes, commoditybased price indexes measure price change for a (wher-ever-provided) service or (wherever-made) good, regardless of the producer's industry of origin. For example, a wherever-provided index for air transportation of freight would measure price change for air transportation of freight from all industries which provide that service. Price changes from industries in which air transportation of freight is classified as either primary production or miscellaneous production would be included in the price index.

In 2006, the BLS began an effort to develop a set of wherever-provided services and construction indexes. This effort included the creation of wherever-provided index weights, the development of an index construction methodology, the identification of the set of detailed whereverprovided indexes whose calculation and publication the BLS could support, and the development of an aggregation and publication structure for the detailed indexes.

## Aggregation and publication structure

Instead of using an established product classification structure, the BLS developed its own publication structure for the new, wherever-provided indexes. Doing so allowed the Agency to build on and remain consistent with its already existing commodity-based structure for goods. The newly developed publication structure includes detailed product-level indexes, as well aggregate indexes that combine detailed price indexes for related services into higher level indexes. In developing the index publication structure, the BLS employed a set of six main principles. This section discusses each of these principles in detail and gives an overview of the publication structure.

Coding structure. Indexes were grouped in accordance with a coding methodology similar to the current PPI commodity structure for goods indexes. Major groupings are coded at the two-digit level, and within these two-digit groupings are more detailed commodity groupings that descend in order of aggregation to the detailed-product level (typically, the eight-digit level).

In order to remain consistent with current practice within the BLS goods-based aggregation structure, in some cases identical indexes are included at various levels of aggregation. For example, PPI 301401 and PPI 30140101 are identical indexes for air transportation of freight. Weight and price data do not support breaking out additional detail under 301401; therefore, no further eight-digit products could be added beneath the six-digit index. Instead, an eight-digit index denoting the same service was added.

Although the current goods indexes encompass the two-digit groupings 01 through 15 , the services groupings were numbered beginning with code 30 . This choice permits a degree of flexibility that otherwise would be unavailable if the services structures began at two-digit group 16, directly following the last goods groupings. There may, for example, come a time when the numbering system for traditional commodities needs to be expanded or reorganized. The final services code in the structure is 60. Following the same line of reasoning, the BLS numbered the construction groupings beginning with twodigit group code 80 .

Similarity of product. Detailed indexes were grouped into higher level aggregates according to similarity of product. Data users often find this type of grouping useful, and the methodology is consistent with the current BLS organizational structure for goods-based commodity indexes, which also groups commodities according to similarity of product. For example, the two-digit index 30 encompasses all transportation services, the two-digit index 40 all investment services.

Avoidance of multiple counting. In organizing the wher-ever-provided services indexes into two-digit groupings, the BLS attempted to avoid aggregations that would result in substantial multiple counting of price changes. Multiple counting, which can lead to inaccurate and distorted measures of price change, occurs when an aggregate index includes not only the price for a product, but also prices for one or more inputs to the product. The wherever-provided structure, for example, includes separate two-digit aggregations, one for transportation services and the other for services related to transportation, because services related to transportation are most often inputs to transportation services. Avoiding multiple counting will permit two-digit services commodity PPIs to provide meaningful information on price changes.

Wherever-provided structure and PPI industry structure. In
developing the index publication structure, an effort was made to develop alternative index aggregations not found in the industry structure. Within transportation services, for example, transportation of freight and mail were separated from passenger transportation. Then, separate aggregate indexes for total passenger transportation services, as well as total freight and rail transportation services, were created. By contrast, within the PPI industry structure, aggregations are based on mode of transportation. The industry structure includes, for instance, an aggregate index for air transportation that combines detailed indexes for air passenger and air freight transportation into a single index.

In a second example, for book, periodical, and newspaper publishing, sales and subscriptions were separated from advertising space sales, and the latter category was combined into a two-digit grouping with advertising from all other media-for instance, television, Web sites, and radio. The industry structure, in contrast, aggregates indexes according to medium. Thus, the industry structure contains an aggregate index for all periodical publishers, and that index combines indexes for sales and advertising from all types of periodicals.

A third example is that the wherever-provided structure separates wired telecommunications into residential services and business services and creates separate aggregate indexes for each. These indexes combine detailed indexes for local and long-distance telecommunications services into either the aggregate residential or the business telecommunications services index. The industry structure, by contrast, aggregates indexes according to long-distance or local telecommunications services.

Partial coverage. Although the PPI covers all industries in the mining and manufacturing sectors, that is not the case in the services or construction sectors. Consequently, higher level aggregate indexes within the wherever-provided structure may be missing products that would be included if the PPI covered all services and construction industries. In cases where the PPI does cover a service area, but not all products under the aggregate area, the index is still published and the term "partial" is added to the end of the index title if the coverage is less than 80 percent. Within the transportation grouping, for example, only about 75 percent coverage exists for passenger transportation services. The PPI covers passenger transportation from air and rail, but does not currently cover boat, bus, taxicab, or several other forms of passenger transportation. ${ }^{3}$

Index reassignment from goods to services structure.
In a
small number of cases, the traditional PPI goods structure contained indexes for services. With the arrival of wher-ever-provided services indexes, the affected services indexes were removed from the goods structure and added to the new services structure. The areas affected by this change were publishing, metal treatment services, and mining services.

Exhibit 1 presents an overview of the publication structure for services and construction up to the threedigit level. ${ }^{4}$

## Weights

An important step in developing the wherever-provided services and construction indexes was to construct a set of weights. The primary data source for these weights was Census Bureau revenue data-specifically, data for "Product Lines by Kind of Business." These data are organized according to the North American Industry Classification System (NAICS) and indicate specific products provided by industries and the revenue value for these products. The products are organized according to Census Product Codes (CPCs). ${ }^{5}$ Note that, with its 2007 Economic Census survey, to be published by 2011, the Census Bureau will have completed its classification of service product-line data according to the North American Product Classification System (NAPCS), and PPI commodity weights for services will then be based on revenue figures from that system. The transition to NAPCS-based weights may result in some structural changes to the wherever-provided services indexes. ${ }^{6}$ However, in order to minimize future structural changes, the BLS reviewed the NAPCS structure while developing both the individual wherever-provided services indexes and the publication structure for those indexes.

Wherever-provided weights were created by aggregating Census Bureau revenue data for individual products, regardless of the providers' industries of origin. For example, the wherever-provided weight for auditing services was constructed by summing the revenues from all the industries that provide auditing services into a single value representing the total revenue of auditing services. (See exhibit 2.)

The 2002 Census of Services classifies auditing services into two product lines: financial auditing services (CPC 34060) and tax auditing services (CPC 35800). Exhibit 2 presents the revenue for both of these products on an industry-by-industry basis. The first and second columns indicate, respectively, the Census of Services product code and title of the service being provided. The third and

fourth columns respectively designate the NAICS code and title of the industry or industry group providing the services. The last column shows the revenue for the specific service. Thus, the first row shows that industry group 541 (professional, scientific, and technical services) produced $\$ 11,243,910,000$ of commodity financial auditing services (CPC 34060) in 2002.

Exhibit 2 shows that the total revenue generated by all industries for financial auditing services in 2002 was $\$ 11,339,564,000$ and that the total revenue generated by all industries for tax auditing services that same year was $\$ 700,415,000$. Therefore, the total 2002 revenue and the wherever-provided weight for auditing services is $\$ 11,339,564,000+\$ 700,415,000=\$ 12,039,979,000$. This figure represents the weight the BLS would assign auditing services within the wherever-provided structure.

## Index construction

This section describes both how the wherever-provided weights are used to construct the commodity-based services indexes and some additional aspects of index construction. The wherever-provided services indexes are calculated by the same methodology that is used for calculating commodity PPIs for mining, manufacturing, agriculture, and utilities.

Like other commodity PPIs, the wherever-provided services indexes are typically published at the eight-digit product level. However, additional detailed indexes are calculated below the eight-digit level, and these indexes are aggregated to create the published eight-digit index. The detailed indexes are created to increase accuracy by allowing for a more precise weighting structure than would exist if just the eight-digit index were calculated.

For a specific commodity, unpublished detailed indexes measuring the average change in the selling price from every industry that is a primary producer of the com-
modity are calculated. In addition, a single index tracking price change in industries in which the commodity does not represent their primary production is calculated. The unpublished indexes are then aggregated into an eightdigit wherever-made index.

Prior to the implementation of the updated PPI estimation system in 2008, the BLS was unable to calculate detailed indexes for nonprimary producers to use in wherever-provided index estimation. The new estimation system allowed for this improvement in index calculation methodology. The new system also resulted in additional improvements for commodity-based calculation, including more accurate monthly weights and the possibility of calculating detailed product indexes not found within the industry-based indexes.

As stated earlier, the PPI does not cover all industries in the services or construction sector. In cases where the index covers some industries producing a specific product, but is missing more than 20 percent of the production of the service, the uncovered weight is removed from the wherever-provided index. As mentioned earlier, the suffix "partial" in the title of the index informs the data user that the index includes only a portion of the wherever-provided service. Conversely, the PPI includes the weight of the missing industry (or industries) within the whereverprovided index in cases where coverage of a specific commodity is at least 80 percent. These indexes are published without the "partial" designation, and the weight is imputed with the use of standard PPI imputation methodology. For the product index, either removing or imputing the weight will yield the same index calculation. For higher level aggregate indexes, however, removing or imputing a commodity index's weight will yield a different result. ${ }^{7}$

Finally, note that the wherever-provided indexes for new construction are methodologically identical to the industry-based new-construction indexes. These two sets of indexes are built from identical weights and share the

Exhibit 2. Example of construction of wherever-provided index weight: auditing services

| Census of Services product code | Census of Services product title | NAICS industry code | NAICS industry title | Revenue (thousands) |
| :---: | :---: | :---: | :---: | :---: |
| 34060 | Financial auditing services | 541 | Professional, scientific, and technical services | \$11,243,910 |
| 34060 | Financial auditing services | 541211 | Offices of certified public accountants | 10,831,314 |
| 34060 | Financial auditing services | 541611 | Administration management and general management consulting services | 394,940 |
| 34060 | Financial auditing services | 541612 | Human resources and executive search consulting services | 4,068 |
| 34060 | Financial auditing services | 541613 | Marketing consulting services | 8,357 |

|  |  |  | total | 700,415 |
|  |  |  | total auditing services | 12,039,979 |

Sources: U.S. Census Bureau, Census of Services, 2002; North American Industry Classification System (NAICS).
same base dates and history. The wherever-provided newconstruction indexes and their respective industry-based indexes therefore will exhibit identical month-to-month percent changes. For construction, the industry and wher-ever-provided indexes are the same because the BLS defines all types of new construction as primary production in all new-construction industries. The wherever-provided construction indexes were developed simply to provide completeness within the commodity-based PPI structure.

With the release of july 2009 data in August, the BLS expanded its coverage of the services and construction sectors of the economy to include wherever-
provided producer price indexes. These indexes track price change for services and construction products, regardless of their industry of origin.

Wherever-provided price indexes add analytical value to the PPI by allowing data users to examine price movements for a specific service or construction product within a single price index that combines prices from all industries producing that product. In addition, detailed price indexes are aggregated into many higher level indexes not found in the industry-based PPI aggregation structure. These wherever-provided aggregations give data users a large number of additional aggregate indexes, thereby further increasing the analytical usefulness of the PPI.

## Notes

[^1][^2]
# The impact of income imputation in the Consumer Expenditure Survey 

With the release of 2004 data from the Consumer Expenditure Survey, the Bureau of Labor Statistics began implementing imputation for missing responses to questions about income; imputation has brought CE estimates closer to CPS estimates, but significant disparities remain between the estimates for many of the smaller components

From 1980, the year the Consumer Expenditure Survey (CE) became a continuous survey, until 2004, no procedures were employed to produce estimates for sources of income that respondents acknowledged receiving, but for which they did not provide values. However, the release of 2004 data marked the introduction of imputation for missing income responses. With a number of years of imputed income data now available, it is possible to evaluate how well BLS imputation routines are working. The purpose of this article is to assess the impact and efficacy of imputation by comparing pre- and postimputation estimates of CE-reported income with estimates from the Current Population Survey (CPS), a large-scale household survey that has employed imputation for many years in the course of producing its income estimates.

In the next section, after a brief discussion of the background and history of income imputation in the CE, the methodology for comparing CE and CPS income estimates is presented. Then the timing of income data collection in the two surveys is examined. Timing is important because
it affects the construction of matching periods for comparison. The discussion then proceeds to detail the structure and content of the income questions asked in each survey's respective collection instrument.

Following the latter discussion, the next section of the article is dedicated to a comparative analysis of aggregate income estimates from the CE and CPS. The common income categories that can be created from the two surveys are detailed, and three alternative estimates of CE income are described. These estimates are then measured against CPS estimates. The analytical portion of this section is devoted to examining both levels and ratios of CE and CPS aggregates, for total income and by income category. The final section of the article briefly summarizes the results of the analysis and notes the direction that future refinements in the collection and imputation of income in the CE are likely to take.

## Background

The CE produces comprehensive expenditure data reflecting the buying habits of U.S. families. Because it is vital that the soundness and consistency of these data be maintained, the

BLS conducts regular, thorough comparisons of CE data with expenditure data from other sources, such as the Personal Consumption Expenditures (PCE) component of the National Income and Product Accounts produced by the Bureau of Economic Analysis. ${ }^{1}$ But a unique feature of the CE which makes it particularly useful is that, as a household survey, it also collects demographic and socioeconomic characteristics of participants that can be associated with the expenditures they make.

Among these characteristics is family income, one of the most important demographic determinants of consumer spending. Household surveys intent on collecting data on family income, either as their primary interest or as supplementary to their primary interest, often encounter the issue of nonresponse because of the sensitive nature of income data. Respondents frequently feel uncomfortable answering questions about their income or may believe that such questions are an invasion of their personal privacy.

Survey managers have resorted to various methods developed by the statistics community for imputing values to substitute for missing responses. These methods make certain assumptions about the distribution of missing values and the relationship of nonresponse to socioeconomic characteristics of the sample population. To the extent that the procedures violate the mechanisms leading to nonresponse, the resulting imputed values will lead to biased and inconsistent results when used for analytical purposes.

CE managers have become particularly sensitive to these concerns because sampled consumer units ${ }^{2}$ report expenditure data that are expected a priori to be highly correlated with income. Consequently, from 1972 to 2003 the CE did not impute for missing income, and CE data releases instead identified sample households as either "complete" or "incomplete" income respondents. ${ }^{3}$

Given the unique requirements that any income imputation procedure would have to satisfy, CE and Census Bureau staff began a systematic search for an appropriate method. Geoffrey Paulin and David Ferraro laid out theoretical and practical issues that would have to be resolved before a method could be selected. ${ }^{4}$ Two general methods for performing imputations merited evaluation. Hot-decking was the technique employed by large-scale surveys such as the CPS. This technique imputes missing income values in the sample with values reported by persons in families with a similar set of demographic and socioeconomic characteristics, predetermined to be relevant to the level of income. Paulin and Ferraro eliminated hot-decking as a method for the CE because of the small sample size of that survey.

The second class of methods examined was modelbased imputation, which draws on the work of Roderick Little and Donald Rubin. ${ }^{5}$ Each of these methods consists of two parts. The first part involves the creation of a statistical model to predict income values, while the second part is concerned with producing error terms to add to the predicted values, thereby preserving the variance of the distribution.

To employ a model-based imputation method appropriately, the response mechanism by which the missing income responses came into being had to be determined first. Little and Rubin laid out three mechanisms. In the first, the missing income responses occur completely at random and are not correlated with any characteristics of the respondents. In the second, the missing responses are correlated with characteristics of the respondents, excluding income. In the final method, the missing responses are correlated with both characteristics of the respondents and the level of income.

In addition, two operational modeling questions had to be answered: first, would income imputation be done at the consumer unit level or at the individual member level within each consumer unit? and second, would imputation be done for total income or for each of the component items of total income?

After researching these questions, Paulin and Ferraro concluded that the second response mechanism, wherein nonresponse is correlated with respondent characteristics only, would be tested first. This testing would then be aimed toward (1) imputation at the consumer unit level, which would avoid complications introduced by interactions involving work decisions between members, and (2) individual components of income, which would provide more information for researchers and allow for differences in model specification and parameter estimates between items.

Finally, Paulin and Ferraro addressed the question of whether expenditures were useful in predicting income and, therefore, should be included in modeling. Testing also would confirm retrospectively whether past reluctance to impute with methods that did not account for expenditures was justified. Paulin and Ferraro found that both total expenditures and expenditures for selected subaggregations of items demonstrated predictive power.

While research continued into the appropriate method for imputing income in the CE, changes were made in the collection instruments in 2001 to improve the reporting of income. Bracketing questions were added to the survey to follow the initial questions. The bracketing questions asked for the amount received for each source of income a
respondent indicated that the consumer unit had received. Thus, if a respondent initially refused to report his or her income or did not know the amount received, the bracketing questions probed to determine whether the respondent would select a range that best reflected the amount received. The responses to the bracketing questions added a layer of complexity to the task of choosing an imputation method.

Once the research was completed, it was determined that the method chosen for the CE would be a regres-sion-based procedure that would preserve both means and variances for each source of income. The process would produce five imputed values for each missing observation. The first step would be to run a regression to obtain coefficients to use in creating imputed values. Random noise would then be added to each coefficient, and the resulting "shocked" coefficient used to estimate an imputed value. Additional noise would be added to the estimated values to ensure that consumer units with similar demographic characteristics would not receive similar imputed incomes. After the five imputed values were created for each missing value, an estimate representing the mean of those five values would be calculated. Reported specific values would be retained as is. If a respondent reported a certain bracket within which his or her income fell, the imputed values would have to fall within the range defined for that bracket.

In a small number of instances, a consumer unit might report not receiving income from any source. In such an extremely unlikely situation, the income imputation procedure would be run with an additional step: a logistic regression based on the characteristics of the consumer unit, such as whether he or she was retired or was a student, would be run first to impute a receipt status (yes or no) for each source of income. For those sources of income that a consumer unit was imputed to have received, the model would be run to produce imputed income values.

## Data collection

The introduction of imputed income in data released from the 2004 CE permits the same kind of comparisons between the CE and other sources that have been made in the past for expenditure items. In fact, by comparing the CE income estimates with those from another established source of income data over a period covering pre- and postimputation years, one can measure both the impact of imputation on the relationship of aggregate CE income to the independent source and the efficacy and quality of the imputation method in producing those estimates. For
this study, CE income data are compared with similar data from the CPS for the 2002-06 period.

Comparisons of mean or aggregate pretax income between the CE and the CPS have been a staple feature of BLS publications for almost 20 years. ${ }^{6}$ Almost all these published comparisons were based on CE data before imputation and CPS data that included imputed values. Income estimates for the CE are from its Interview Survey component, while the Annual Social and Economic Supplement (ASEC) is the source of CPS income data for comparison in this study.

The difference in timing of the collection of income data between the CE and the CPS poses challenges in constructing matching periods for comparison purposes. The Interview Survey is designed to collect one year's worth of expenditure data from sample units. This is done through five interviews, the first interview for bounding purposes only and the remaining four interviews conducted at 3month intervals, thereby collecting expenditure data for 12 months. The Interview Survey uses a rotating design whereby sample units are introduced every month (replacing other units that have completed their participation in the survey.) Income data are collected during the second and fifth interviews, covering the 12 months prior to the month of the current interview. Thus, a consumer unit undergoing the second interview in June 2007 would report wage income received from June 2006 through May 2007.

The ASEC is conducted annually in March, although a limited number of eligible households are interviewed in February and April. The survey collects data on the previous calendar year's income from all sources. Thus, households completing the ASEC in March 2007 report income for the 2006 calendar year. Conducting the ASEC in March is believed to provide better income data, because most households would either be in the process of completing or have just completed preparing tax returns and therefore would be more likely to remember income sources and amounts.

Although the structure and wording of income questions are similar in the CE and the CPS, there are major differences that can affect the estimates. In the CE, the respondent is asked to report the amount received from earned income, Social Security, Railroad Retirement, and Supplemental Security Income individually for each consumer unit member aged 14 years and older. For each of the remaining sources of income, the respondent reports the amount received by the consumer unit as a whole. In comparison, in the ASEC the respondent is directed to report individually the amount received for each source
of income by each household member 15 years or older. Regarding income reference periods, the CE respondent is asked about the amount received over the last 12 months for each source of income, with the exception of Social Security and Railroad Retirement income, for which the respondent reports the amount of the last payment received. If the respondent either refuses to answer or does not know the amount received for any of these sources, he or she is shown a card with ranges or brackets of income and then is asked to report which bracket best reflects the amount received. In the ASEC, respondents are asked to report the amount received over the calendar year. If they find that a year is too big a time span over which they can exercise recall, they are allowed to report for shorter periods. The periodicity of their response is asked if necessary.

## Sources of income

With respect to the contents of the income questions, and using the CE questions as a basis for comparison, one readily sees that it is natural to consider earned income first, because it is by far the largest contributor to total income. The questionnaire in the Interview Survey asks the amount each eligible member of the consumer unit received in wages and salaries (including commissions, tips, allowances, Armed Forces pay, severance pay, teaching fellowships, and the like) for all jobs. The Interview Survey also collects data in a separate question on income or losses after expenses from each consumer unit member's unincorporated nonfarm business, partnership, or professional practice, as well as income or losses from the consumer unit's own farm. The ASEC asks for earnings, including tips, bonuses, overtime pay, and commissions, from the employer for whom the member worked longest during the calendar year. Such earnings can be wage and salary income, net income (or loss) from nonfarm self-employment, or net income (or loss) from farm self-employment. Three followup questions probe for earnings from other employers, other nonfarm businesses, and other farms. Severance pay and military allotments are included in earnings, and questions on these topics are asked in combination with questions on other miscellaneous sources of income after the questions for all other specific income categories have been asked.

The CE probes for amounts of Social Security and Railroad Retirement income received. These amounts include survivor and disability insurance payments, as well as retirement benefits. The ASEC asks separate questions about Social Security income and Railroad Retirement income. Data on Social Security income are obtained
from a question on payments received by the household member directly or on behalf of children under age 19 in the household. Data on Railroad Retirement income are collected in questions covering three broad categories of income for which an individual may be eligible under the program: pension or retirement income, survivor benefits, and income related to a health condition or disability.

Supplemental Security Income (SSI) is one of the few sources of income for which the CE and ASEC questions are essentially the same. Both surveys ask for the amount of SSI received from all government sources. Questions collecting data on interest income in the CE and ASEC also are quite similar. The only difference is in the potential sources of interest income referenced in the questions. The Interview Survey probes for interest from bank accounts, money market funds, certificates of deposit, or bonds, whereas the ASEC uses three questions that specifically screen for whether any members of the household have received any interest from money market funds, interestearning checking accounts, savings accounts, cashed savings bonds, treasury notes, individual retirement accounts (IRAs), certificates of deposit, or other investments that pay interest.

In one of its questions, the CE queries respondents for amounts of regular income from dividends, trusts, estates, or royalties. The types of income cited in this question also are found in a number of places in the ASEC questionnaire. One question is specifically directed toward dividends from stocks and mutual funds. Data on receipts from estates or trusts are collected in two places. The first is as a source of survivor benefits, the second as a class of property income. Data on net royalty income also are collected in the latter question.

Data on pension and annuity income, whether due to retirement, due to disability, or as a survivor, are collected through one question in the CE Interview Survey. Sources specified for such income are private companies, the military, government, IRAs, and Keogh plans. As mentioned earlier with regard to Railroad Retirement income, the ASEC inquires about retirement and pension income, survivor benefits, and disability income in separate questions. The question about retirement and pension income refers to all such income from a previous employer or union, or any other type of retirement income from sources other than Social Security or veterans' benefits. With the exception of retirement income from Railroad Retirement, the income data collected here conceptually match CE counterpart data.

The ASEC query on survivor benefits also mentions widows' pensions, insurance annuities, and other survivor
benefits (other than Social Security or veterans' benefits). Income from survivor pensions from private companies; unions; Federal, State, and local governments; and the military are reported here. The ASEC questions concerning income related to a health condition or disability identify many of the same sources that are listed for survivor benefits, such as companies, unions, government at all levels, and the military. Finally, though not explicitly stated in the question, income received from foreign government pensions is offered as an example of one of the types of income the miscellaneous income question at the end of the ASEC is designed to capture.

Unemployment compensation and supplemental unemployment compensation are other sources of income cited in the CE Interview Survey questionnaire. The ASEC poses three separate questions on unemployment compensation. One asks for the amount of State or Federal unemployment compensation, the second probes for income from supplemental unemployment benefits, and the third focuses on union unemployment or strike benefits.

The CE asks respondents to combine income received from worker's compensation or veteran's benefits, including the GI bill, but excluding military retirement benefits, in one report. Worker's compensation is surveyed in a distinct question in the ASEC, but the question also covers any other payments made as a result of a job-related injury or illness. Worker's compensation benefits, including benefits for black lung disease, also are reported in the aforementioned ASEC questions on survivor benefits and disability income. The receipt of veterans' benefit payments warrants its own question in the ASEC, but not in the CE.

Another question in the CE Interview instrument pertains to income received as public assistance or welfare. In 2002, the questionnaire used Aid to Families with Dependent Children and grants from Job Corps as examples of such assistance. In subsequent years, the questionnaire was revised to refer specifically to cash assistance from any State or local government welfare program, such as Temporary Assistance to Needy Families, or short-term emergency help. The main question that seeks this information in the ASEC probes for cash assistance received from a State or county welfare program (with the name of a representative State program added as an example), either directly or on behalf of children in the household. The miscellaneous-income question at the end of the ASEC lists welfare, emergency assistance, and other shortterm cash assistance as examples of the types of income to be reported.

Two questions in the CE Interview Survey instrument
cover any net income or loss from any type of rental of rooms or living units. The first question is directed toward collecting data on net income or loss from roomers or boarders; the second focuses on ascertaining data on net income or loss received from other rental units. The property income question in the ASEC, which was heretofore mentioned as a source for trust/estate and royalty income, also seeks information on net income or loss from rental property and receipts from roomers and boarders.

Child support payments not received as a lump sum are an additional component of income found in the CE Interview Survey. A similar question appears in the ASEC.

The CE Interview Survey questionnaire asks about regular income from alimony or other sources, such as income from persons outside the consumer unit. The ASEC splits these sources between two questions, the first referring to alimony payments, the second to regular financial assistance from friends or relatives not living in the household.

Finally, the CE Interview Survey poses a catchall question seeking information about "other" money income. Among the sources from which this other money might have been received, the question lists cash scholarships and fellowships, stipends not based on working, and the care of foster children. All other income from a source not specified in previous questions is to be reported here. The ASEC contains a question requesting information on educational assistance for tuition, fees, books, or living expenses, including Pell Grants. Listed in this question as sources of educational assistance are scholarships and grants, as well as employers, friends, and relatives living outside the household. Assistance from any of these sources could be reported in a number of places in the CE. To the extent that a student is receiving regular payments, such payments would be reported as regular income from sources outside the consumer unit. If the assistance is earmarked for a particular educational expense, such as tuition, it could be reported in the educational expenses section of the CE as an expenditure for which reimbursement is received. The miscellaneous-income question at the end of the ASEC encompasses payment for caring for a foster child, as well as any other money income not already covered by earlier questions.

The ASEC is designed to cover the civilian noninstitutional population, plus those military personnel who live with at least one other civilian adult, on or off base. The CE also is designed to represent the civilian noninstitutional population, plus a portion of the institutional population: residents of boarding houses; those living in student or worker housing facilities, such as college dormitories;
staff units in hospitals or in homes for the aged, infirm, or needy; and those residing in permanent living quarters in hotels, motels, or mobile home parks. Nursing home residents are excluded, as are military personnel living on base. Off-base military personnel are included.

## Comparison of CE and CPS income

Sources and timeframes. ASEC income data used in this article are derived from an unpublished Census table titled "In-House Table 8. Income Allocation by Income Source," which the CPS produces annually for its internal use. For each source of income, the table shows the number of persons 15 years and older (in thousands) who receive income from that source and the mean amount of income they receive. Both those directly reporting income and those for which allocation is done are covered. In Census parlance, allocation is the equivalent of imputation in the CE. The means and numbers of persons reporting each source of income are multiplied together to obtain aggregate income.

The income categories shown here are the most detailed that can be constructed from the types of income provided in table 8 from the ASEC and the income Universal Classification Codes from the CE. ${ }^{7}$ Total aggregate income is composed of the following categories: wage and salary income; net nonfarm self-employment income; net farm self-employment income; unemployment compensation; workers' compensation (including compensation for black lung disease) and veterans' benefits; Social Security and Railroad Retirement income; Supplemental Security Income; public assistance; pensions and annuities; interest; dividends, rents, royalties, and estates and trusts; child support; and accident and temporary insurance, educational assistance, alimony, financial assistance, and other income not elsewhere classified.

As noted earlier, annual estimates of income for the CPS match the calendar year, while the annual estimates of income for the CE Interview Survey cover the year prior to the month of interview. Thus, a major issue in comparing CE and CPS income estimates is determining how to select consumer units for inclusion in the analysis. After due consideration, three estimators of CE income were chosen.

The first replicates the method used for producing income estimates in the CE-CPS income comparison tables (and the reference tables) that appear in CE publications. ${ }^{8}$ Recall that the CE Interview Survey collects expenditure data for the 3 months prior to the interview month; annual income reported by consumer units in their second
or fifth interview is adjusted to fit the same period. In practice, this means dividing the annual amount by 12 , thus creating a monthly amount, and then assigning that amount to each of the 3 months covered by the interview. For example, if a consumer unit reports $\$ 600$ of interest income at its second interview in March 2006, this process will assign $\$ 50(\$ 600 \div 12)$ to each of the months from December 2005 through February 2006, the reference period for the interview. Second-interview income is carried forward through the third and fourth interviews before the income data are collected again at the fifth interview. Thus, at its third interview in June 2006, the aforementioned consumer unit would have $\$ 50$ of interest income assigned to each of March, April, and May of 2006. The annual CE estimate for any calendar year will be calculated from all income assigned to that year.

Compared with the CPS estimate, the estimate created by this method uses a significant amount of income reported from an earlier period. With 2006 as an example, the first month whose interviews would be used in the CE estimate is February. One-twelfth of the income reported in that interview would be assigned to January. However, the 12 -month reference period for reporting would run from February 2005 through January 2006, meaning that 11 months of the reference period would have been outside the calendar year of interest. April 2006 would be the first month in which one-twelfth of the annual income reported would be allocated to a 3-month reference period in which each month would be in 2006 (January-March). Yet the recall period for income in the April 2006 interviews is April 2005-March 2006, a full 9 months of which still are outside the year of interest.

In fact, the only month whose interviews would span a recall period matching the ASEC calendar year is January of the next year. (For calendar-year 2006, interviews conducted in January 2007 would have an annual reference period from January 2006 to December 2006.) This fact forms the basis for the second method of creating CE estimates for comparison with CPS income estimates: only the second and fifth interviews conducted in January of the next year are used to construct the estimate. Although using such interviews would exactly match the period covered by the ASEC, the number of interviews is very small-about one-sixth of the number of interviews conducted in any one quarter. This small number of interviews would be detrimental to the statistical reliability of the estimate, potentially leading to wide annual swings in it, particularly for some of the more thinly reported categories of income.

Because of the conceptual attractiveness of the sec-
ond method in matching the ASEC timeframe, the third method for creating CE estimates essentially expands on the second method. Centering on January interviews, this method adds the second and fifth interviews conducted between October of the previous year and April of the current year, or 3 months before and after January, to expand the number of interviews used in creating the estimate. As a result, one-seventh of the interviews report income earned in the year matching the calendar year. The earliest 12 -month period, reported by one-seventh of the interviews, would run from October 1 of the previous year to September 30 of the current year; similarly, another one-seventh of the interviews would cover the latest 12month period, from April 1 of the current year through March 31 of the next year.

In all three methods, weighting adjustments are made to ensure that the aggregate estimates are representative of the entire population. The adjustments start with the fact that sample units in the CE Interview Survey are assigned population weights such that the sum of the weights for consumer units interviewed in a calendar quarter will equal one national population. Thus, for any month, the sum of the weights of interviewed units will be approximately one-third of the national population and the sum of the weights of units undergoing a particular interview-the second, third, fourth, or fifth-during that month will approximate one-twelfth of the national population.

To obtain a population-weighted estimate of CE income by the first method is straightforward because of the way annual income is mapped to the reference months of each interview. For example, all income assigned to March 2006 would originate in interviews conducted from April through June of 2006. The weights assigned to consumer units interviewed during those 3 months would approximate one national population. Thus, one can calculate a nationally representative estimate of March 2006 income by applying the weights to the income reported. This procedure can be extended to each month of a calendar year, and then a weighted annual estimate for each year can be derived by summing the monthly estimates.

The weighting adjustment for the second method of estimating CE income also is fairly simple and is expanded to apply to the third method. The second method uses the second and fifth interviews in January of a survey year. These interviews represent approximately one-sixth of the interviews conducted in the first quarter of the year; thus, their weights are multiplied by 6 to produce a weighted national estimate. In the third method, the weights for the second and fifth interviews taken over the 7 months from October to April would represent about one-and-
one-sixth times the national population. Rather than deflate them all equally, it was decided that the weights for units undergoing their second and fifth interviews in the outlying months of October and April would be cut by one-half. This decision would be simple to implement and would assign greater weight to interviews conducted in months closer to the central month of January.

Results. The impact of imputation in the CE can be seen in table 1, which shows aggregate incomes, total and by source, from the CE and CPS, along with the ratio of CE-to-CPS estimates for the years 2002-06. The CE did not impute for income nonresponse in the first 2 years of this period, so the estimates are based on all reported income, regardless of whether the consumer unit was considered a complete or incomplete income respondent.

Imputation significantly raises CE aggregate income, bringing it into near comparability with CPS estimates. On average, imputation adds about 20 percentage points to the CE/CPS ratio. For the preimputation period of 2002-03, the mean CE/CPS ratio for total aggregate income, taking into account each method for estimating CE income, is about 0.75 . The average ratio for the postimputation period of 2004-06 rises to about 0.95 .

This increase in the ratio for aggregate income is driven largely by the increase in wage and salary income after imputation in the CE. Wage and salary income accounts for about 80 percent of total CE income and 77 percent of total CPS income over the 2002-06 period. Before imputation, CE aggregate income averages about $\$ 1,650$ billion less than CPS aggregate income, with CE wage and salary income trailing CPS wage and salary income by about $\$ 1,123$ billion. The CE/CPS ratio for wage and salary income averages about 0.78 . After imputation, the gaps between aggregate income and wage and salary income in the CE and CPS narrow to an average of about $\$ 462$ billion and $\$ 179$ billion, respectively. Wage and salary income for the CE almost matches the CPS estimate, with an average ratio of about 0.97 .

Social Security and Railroad Retirement income is the next-largest component of total income in the CE and CPS. The story here is similar to the one for wage and salary income. The mean 2002-03 CE/CPS ratio is somewhat more than 0.80 , while the 2004-06 ratio increases to slightly more than 0.95 .

Imputation in the CE has a larger impact on the CE/ CPS ratio for nonfarm self-employment income, the thirdlargest contributor to total income, than for any other component of income. In fact, the ratio almost doubles after imputation, going from about 0.63 to a bit more than

Table 1. Continued-Aggregate pretax income and ratios for Current Population Survey (CPS) and for three alternative measures for Consumer Expenditure Survey (CE), by total and source of income, 2002-06
[In billions of dollars]

1.22, making nonfarm self-employment income the only source of income for which the CE estimate is, on average, higher than the CPS estimate.

At about 4 percent of the total, pension and annuity income is the next-largest component of total income. After imputation, the CE/CPS ratio for pension and annuity income rises by an amount that is almost equivalent to that for Social Security and Railroad Retirement income.

For 2002-03, the ratio averages just under 0.81, increasing to slightly under 0.93 for 2004-06.

None of the nine remaining income components represents as much as 2 percent of total income reported in the CE. For the CPS, however, two categories-interest income; and income from dividends, rents, royalties, and estates and trusts-each make up more than 2 percent of total income. Hence, the CE/CPS ratios for these items are
fairly low, and, historically, they have been among the lowest in the published tables. In addition, interest income is one of the few components whose CE/CPS ratio does not increase appreciably after imputation: on average, the aggregate preimputation interest income estimate in the CE is about 28 percent of the CPS estimate, while, after imputation, the estimate increases about 3.5 percentage points, to just under 32 percent of the CPS estimate.

Imputation does not have a marked impact on the CE/CPS ratio for income from dividends, rents, royalties, and estates and trusts either, although the initial level of the ratio is higher than that for interest income. The ratio for 2002-03 averages midway between 0.42 and 0.43 , and increases to an average of just over 0.47 after imputation.

Each of the remaining seven sources of income accounts for less than 1 percent of total income in each of the CE and the CPS. Thus, any change in the CE/CPS ratio after imputation has a tiny impact on overall aggregate income between the two surveys. In addition, the number of consumer units in the CE reporting income from these sources is often very low, particularly for the method of creating CE estimates from the second and fifth interviews from January of the next year. Hence, outlying values have a disproportionate impact on the calculated estimates.

Of the seven components still outstanding, two actually show a drop in the average ratio between 2002-03 and 2004-06. The first of these is farm self-employment income, for which the CE-CPS ratio drops almost 3 percentage points, from slightly under 54 percent to 51 percent. The other component is an amalgam of individual income sources from each survey that could be combined into the category of accident and temporary insurance, educational assistance, alimony, financial assistance, and other income not elsewhere classified. The CE/CPS ratio for this component shows an even larger change between pre- and postimputation periods, dropping from an average of about 0.74 to approximately 0.66 . For both of these components, and more strikingly for the latter, the wide swings in the CE estimates across years in the second and third estimation methods are due to infrequent reports of such income, a factor that offers an explanation for the drop in the ratio.

Examining the five remaining sources of income reveals, on the one hand, that the mean CE/CPS ratio for unemployment compensation rises significantly after imputation. The CE estimate for 2002-03 averages almost 48 percent of the CPS estimate. For the 3-year period after imputation is introduced, the CE estimate rises to an average of more than 64 percent of the CPS estimate. On the other hand, for income from workers' compensa-
tion (including compensation for black lung disease) and veterans' benefits, the ratio of CE to CPS income changes very little after imputation, moving from about 0.22 to more than 0.24 .

SSI is another income component for which the average ratio remains relatively stable subsequent to imputation. At a mean of about 70 percent of the CPS estimate in 2002-03, the CE estimate for SSI is the fifth highest among the components with respect to the CPS. Adding imputed SSI income to that reported by consumer units increases the CE estimate only to an average of somewhat under 74 percent of the CPS estimate during 2004-06. By contrast, child support income, a marginally smaller component of total income than SSI, exhibits a large increase in the CE/CPS ratio after imputation: the ratio averages slightly more than 0.65 for 2002-03, after which it rises to an average of well over 0.76 over the 3 -year period that followed. The final and smallest source of total income, public assistance, displays the largest rise in the CE/CPS ratio after imputation began. The CE estimate averages under 61 percent of the CPS estimate in the 2 years prior to imputation, rising over the next 3 years to an average of slightly more than 86 percent of the CPS estimate, a greater-than-25-percentage-point increase.

## The role of imputation

The preceding examination of the change in the ratio of CE income to CPS income after CE income estimates are augmented by imputation shows only part of the picture with respect to the impact of imputation on the relationship between the two measures. This section investigates more closely the magnitude of imputation as it affects the final aggregate estimates for total income and for each source of income in the CE and the CPS over the 2004-06 period when imputation is done for both surveys.

Table 2 shows the percentage of CE and CPS aggregate income, both total and by source, accounted for by imputation for the 3 years during which it has been used in the CE. An examination of total income shows that about 37 percent of the CE aggregate is attributable to imputation, compared with about 33 percent in the CPS. On average, the percentage of imputed income in the CE has risen each year since the inception of imputation, while the percentage has remained stable in the CPS. Even though the CPS aggregates are larger than the CE aggregates and the difference between the aggregates has risen from approximately $\$ 400$ billion in 2004 to about $\$ 530$ billion in 2006, the dollar amounts imputed in the CE are uniformly larger than the amounts imputed in the

${ }^{1}$ Less than 0.1.

CPS and the difference in imputed aggregate income has risen from about $\$ 35$ billion in 2004 to around $\$ 260$ billion in 2006.

As noted earlier, wage and salary income is the predominant component of total income, so the contribution of imputation to aggregate wages and salaries essentially matched the contribution to total income. Imputation is a bigger factor in the CE estimates than the CPS estimates, in terms of both the percentage of the estimate and the actual dollar value. In 2004, 37.0 percent of CE wages and salaries are a result of imputation, and the percentage rises to 37.2 percent in 2005 and 39.0 percent in 2006. Over the same 3 years, imputation accounts for about 30.1 percent of CPS wages and salaries. Wages and salaries imputed in the CE exceed those imputed in the CPS by about $\$ 220$ billion for 2004, rising to about $\$ 475$ billion in 2006.

The two components of total income representing retirement income show remarkably similar patterns with respect to the effect of imputation, both internally and in relation to the CPS. Though starting from a lower level, the average percentage of imputed income represented in the CE estimates for Social Security and Railroad Retirement income and for income from pensions and annuities
increases each year from 2004 to 2006. For the former component, the percentage goes from 20.2 percent to 23.2 percent; for the latter component, it rises from 18.3 percent to 23.8 percent. Nonresponse appears to have been less of an issue for the CE than for the CPS, because the CPS is seen to have imputed, on average, 33.6 percent of Social Security and Railroad Retirement income and 32.8 percent of pensions and annuities over the 3 -year span. With one exception, the income directly reported by respondents is $\$ 30$ billion to $\$ 55$ billion more for Social Security and $\$ 10$ billion to $\$ 60$ billion more for pensions and annuities in the CE than in the CPS.

More than one-half of the CE estimates for nonfarm self-employment income are derived from imputation. As with the sources of income mentioned in the previous two paragraphs, the average percentage of imputed income rises each year, but there is a sizable 11-percentage-point increase, from 57.5 percent to 68.5 percent, between 2005 and 2006. Imputation in the CPS averages 42.7 percent over the 3 -year period. The amount imputed in the CE estimates is significantly greater than the amount imputed in the CPS each year, although, seemingly paradoxically, the average difference is smallest, at just over $\$ 103$ billion,
in 2006, the year in which imputed income makes up the largest proportion of the CE estimate.

Interest income and, to a lesser degree, income from dividends, rents, royalties, and estates and trusts show wildly different response patterns between the CE and the CPS. The percentage of imputed income incorporated into the CE estimates for interest income has varied from 45.8 percent in 2004, to 58.6 percent in 2005 , to 55.9 percent in 2006. The change in the percentage from year to year is attributable to swings in the percentage of income imputed in the CE estimate that is derived from January interviews only. The CPS derives an average of 72.0 percent of its annual estimates from imputation, and the actual dollar amounts imputed dwarf the amounts of imputed interest income in the CE by $\$ 100$ billion to $\$ 120$ billion.

The average percentage of imputed income for CE dividends, rents, royalties, and estates and trusts over the 2004-06 period peaks in 2005 at 41.0 percent and then drops the next year to 33.4 percent, the lowest of all 3 years. In 2004, imputed income makes up 36.4 percent of this category. CPS estimates for dividends, rents, royalties, and estates and trusts are composed of a higher percentage of imputed income-on average, about 48.6 percent-than is any CE estimate produced for the same period, with one exception: the 2005 CE estimate based on January 2006 interviews. In actual dollar amounts, the CPS uniformly imputes much higher amounts than does the CE, regardless of the way CE income is measured: on average, $\$ 83.2$ billion dollars are imputed annually in the CPS, compared with $\$ 29.6$ billion in the CE.

Turning to the two components whose CE/CPS ratios fall after imputation is instituted reveals that the first-farm self-employment income-shows average percentages of CE imputed income rivaling the levels for nonfarm self-employment income. For both 2004 and 2006, almost 60 percent of CE farm self-employment income originates as a result of imputation, slightly more than the 54.8 percent of the farm self-employment income estimate imputed in 2005. The CPS imputes about $\$ 10$ billion more of farm self-employment income than the CE imputes annually, although, as a percentage of the total, the CE and the CPS imputations differ by less than 2 percentage points ( 58.0 percent and 56.8 percent, respectively).

Imputation constitutes a much smaller proportion of CE income for the second category: accident and temporary insurance, educational assistance, alimony, financial assistance, and other income not elsewhere classified. The average percentage of imputed income for this category ranges from 21.9 percent in 2004 to 33.9 percent in 2005.

The amount of income imputed by the CPS for the same category averages twice as much ( $\$ 25.7$ billion compared with $\$ 12.8$ billion) as the amount imputed in the CE across all of the years examined. As a proportion of the total, imputed income makes up 37 percent in the CPS and 28.6 percent in the CE.

Over the 2004-06 period, the annual average percentages of income imputed for unemployment compensation in the CE are fairly low and stable: 26.6 percent in 2004, 23.0 percent in 2005, and 28.6 percent in 2006. However, a closer examination of the imputation percentages for each method of selecting CE observations shows that imputation is much more prevalent when January interviews alone are used, adding up to 6 percentage points to the average. Overall, the percentages imputed in the CE and the CPS are similar, differing from about 1 to 3 percentage points across the years studied.

For the category of workers' compensation (including compensation for black lung disease) and veterans' benefits, tracking the average percentages imputed in the CE is somewhat misleading. In 2004 and 2005, the average percentages of income imputed are 18.2 percent and 16.2 percent, respectively. The average percentage almost doubles in 2006, to 32.0 percent. These results are due almost solely to the relative paucity of imputation in estimates based on January interviews. In 2005, barely any income from this source- 0.6 percent-is imputed for January 2006 interviews. For the estimate based on interviews during the period from October 2005 to April 2006, the percentage imputed is 25.8 percent, and for the estimate based on the publication methodology, 22.2 percent results from imputation. In 2004, the situation is similar, though not so extreme. The respective percentages imputed are 26.5 percent (publication method), 20.1 percent (October 2004-April 2005), and 7.9 percent (January 2005). A complete reversal of this pattern occurs in 2006, with the percentage imputed for January 2007 interviews leaping to 44.4 percent while the percentages for the publication method and the October 2006-April 2007 interviews are 28.6 percent and 22.9 percent, respectively, comparable to the rates posted in the earlier 2 years. Imputation in the CPS accounts for about 30.9 percent of such income, compared with 24.4 percent of income derived for the latter two methods in the CE.

On average, the percentages of SSI imputed in the CE are the second lowest of any component of total income. Although imputed income makes up an increasing share of the total each year of the period examined, the overall rise is small, going from 15.5 percent in 2004 to 17.8 percent in 2006. CPS percentages of imputed income are
about 10 points higher than those in the $\mathrm{CE}(26.9$ percent, compared with 16.7 percent), with actual dollar values imputed running more than twice as high as the CE's ( $\$ 8.4$ billion, compared with $\$ 3.9$ billion).

Imputation in the CE for income from public assistance shows the interyear variability exhibited by other components, such as accident and temporary insurance, educational assistance, alimony, financial assistance, and other income not elsewhere classified, as well as interest income. The average percentage imputed swings from 22.2 percent in 2004, down to 17.9 percent in 2005 , and then up to 29.7 percent in 2006 . As with these other sources, the variability in the case of income from public assistance can be traced to changes in percentages imputed for January interviews. The percentage of income resulting from imputation in the CPS is greater than that of the CE for the first 2 years of the period, but lower than the CE's estimate for the final year.

The final component of total income, child support, shows both the lowest and most consistent average percentages of imputed income as a share of the total of any component of income in the CE. In 2005, only 10.2 percent of child support income-the lowest average percentage of the three years examined-is obtained via imputation. The highest percentage, only about 1.6 percentage points greater than the lowest, is 11.8 percent of the total, registered in 2004. The CPS imputes a much higher percentage of child support over the period, an average of 27.1 percent, more than 3 times as much, on average, in dollar terms: $\$ 7.1$ billion, as opposed to $\$ 2.1$ billion.

With the release of 2004 Data from the Consumer Expenditure Survey (CE), the BLS began implementing imputation for missing responses to income questions. The multistage procedure produced multiple imputed values for each missing observation. To assess how well
these imputation routines performed, estimates of aggregate income based on both reported and imputed values were compared with estimates calculated from the Current Population Survey (CPS) for the years 2002-06. This period covered the 2 years prior to the introduction of imputation and the 3 years following.

Because of methodological differences between the CE and the CPS, three alternative measures of CE income were derived for comparison with the CPS. On average, prior to imputation CE estimates for total money income before taxes were about 75 percent of the CPS aggregate. After imputation, CE estimates rose to about 95 percent of the CPS estimate. An examination of individual sources of income reveals that, in general, imputation has brought CE estimates closer to CPS estimates, although significant disparities remain between the estimates for many of the smaller components. On the basis of these results, further refinements to the CE income questions and imputation procedures are expected.

The analysis presented in this article has used the Annual Social and Economic Supplement (ASEC) of the CPS as a benchmark to which CE Interview Survey aggregates are compared. The Census Bureau, in its turn, evaluates the quality of ASEC estimates through comparison studies with other independent sources of income. In a similar vein, Daniel Weinberg has cited studies comparing CPS income data with national and State income data from the Bureau of Economic Analysis, with income data from the Census Bureau's Survey of Income and Program Participation, and with earnings data from the Internal Revenue Service. ${ }^{9}$ Also, Bruce Webster has compared median household income and earnings estimates for 2004 and 2005 from the American Community Survey with CPS data. ${ }^{10}$ Comparing CE income estimates with these alternative sources, in addition to continuing work with the CPS, offers further avenues for analyzing the quality of CE income data.

## Notes

ACKNOWLEDGMENT: Thanks go to Carmen DeNovas-Walt and Edward Welniak of the Income Surveys Branch of the U.S. Census Bureau for providing the CPS income data and reviewing the manuscript of this article.

[^3]persons living together who use their incomes to make joint expenditure decisions. Financial independence is determined by spending behavior with regard to the three major expense categories: housing, food, and other living expenses. To be considered financially independent, the respondent must be financially responsible for at least two of the three major expenditure categories, either entirely or in part.

## 'Tis the season for learning

The Race Between Education and Technology. By Claudia Goldin and Lawrence F. Katz. Cambridge, MA, Harvard University Press, 2008, 488 pp., \$39.95/hardback; \$19.95/paperback.

This major work by two Harvard University economists argues that wealth creation in the United States was a direct result of the education of the masses of its citizens. They propose that the first 75 years of the 20th century could in fact be called a "human capital" period, in which most of today's productive technologies were created and successfully applied, leading to progressively higher standards of living. During the last quarter of the century and stretching into the 21st century, however, the U.S. began to lag behind other countries in a number of measures of educational achievement. The authors contend that this lag, in combination with the ease of international transfer of technology to lower cost countries, challenges America's ability to compete in the world market.
The case for investing in human capital is well developed and persuasive in this book. The evolution and spread of high schools are what the authors term "the virtues" that led to economic success. The virtues are 1) ample funding of public education through high school 2) decentralization, with ever more numerous school districts 3 ) separation of church and state, promoting an educational experience common to all American youth 4) gender neutrality and 5) a measure of permissiveness in making up for failed grades or missed schooling opportunities. These virtues, the authors contend, contrasted posi-
tively with the more elite systems of European countries, where tests were usually imposed at an early age that mandated placing youngsters on divergent and often inferior educational tracks.
Known in the early 20th century as the High School Movement, "Americans pioneered the modern secondary school...(and) tailored it for the masses." As early as 1920 a high school or college education was expected in 25 percent of all jobs, largely owing to the rapidly increasing need for whitecollar workers. Successive cohorts of students benefited from educational attainment exceeding that of their parents. Since 1980, however, the "human capital stock of the work force" has grown more slowly, reflecting "the slower rate of increase of educational attainment for post-1950 cohorts." Some uncertainty about the continued viability of the "virtues" also colors the last parts of the authors' relevant discussion, given such matters as the contentiousness over unequal financing of school districts, for example.
But the authors' chief concern remains the slowing of mass college education in relation to the need they postulate for a forward-racing technology. This concern is strongly motivated by worry about the widening inequality gap in the distribution of income since the 1970s and its regressive social and economic implications. During the 1947-1973 period family incomes rose rapidly; the distribution of income tended to favor those at the bottom while retarding growth at the top. After the mid-1970s, income generally grew more slowly for most Americans but at a much faster clip in the top quintiles (or deciles). Moreover, the link between the ad-
vance in productivity-output per hour worked-and family income weakened; in fact, real median family incomes fell well behind gains in productivity. Thus, "the benefits of economic growth are now far less equally shared than in the past."

The authors trace the changes in the distribution of income to a growing inequality of earnings in the labor market. The labor market includes high-paid corporate executives, of course, but also middle- and low-income workers and unemployed persons looking for paid work. The authors present detailed analyses of the widening distribution of wage/salary incomes, not only between different skill groups but also within the same occupational, skill, and experience groups. This gap is truly an unprecedented phenomenon which requires much further research and explanation.
The authors' discussion of the rise in the college/high school premium is instructive. This premium more than doubled between the 1980s and the early 2000s, indicating strong rising returns to education. The four reasons thought to underlie this development are 1) intensified computerization, leading to a demand for highly-skilled and educated workers (although the authors disagree somewhat on the extent of the demand), 2) globalization and international trade, leading to outsourcing of labor-intensive jobs to lower wage countries and, simultaneously, putting downward pressure on the wages of lesser educated workers in the United States, 3) slowing growth in educational levels of post1950 cohorts, causing a demand-supply imbalance in favor of educated workers and, 4) the weakened bargaining power of trade unions.

The authors feel that these reasons are an implicit rejection of the widespread belief that the demand for more educated workers has been linked solely to the skill-biased technology associated with computeriza-tion-a topic they discuss at some length. They feel that the proponents of this explanation ignore the historical evidence. True, we still witness technological change today, but these changes are quite ordinary in comparison to those experienced during the first decades of the 20th century. As a result of the "electric motor spread," for example, manufacturing horsepower in the form of purchased electricity rose from 9 percent in 1909 to 53 percent in 1929. Numerous new consumer goods-such as appliances, vacuum cleaners, radios, and automobiles-emerged in the market between 1900 and 1925, bearing witness to the productivity advances and the skill and education of the workers designing and fabricating them. In terms of today's skill-based technological change, the authors contend
that "the era of computerization has brought little that is new;" in fact, they allude to certain reductions in skill bias which they call "deskilling." They cite "the substitution of office machinery for skill" as contributing to the "compression" of clerical workers' wages. Many other examples might be mentioned in which computerization simplified tasks, requiring little skill from the worker performing it (retail checkout comes to mind). Task simplification has become a core characteristic of work organization; it has become a condition of economies of scale, which long ago spread from manufacturing to service industries. Good for productivity, perhaps, but not so good for stimulating new ideas and inventions.
The case the authors make for improving the skill and education of the work force as key elements of economic growth, founded on a wealth of data, is well made. Their case for the need of a much enlarged college or university attendance, however, would have been stronger had they
related it to the deeply unequal distribution of gains from advancing productivity. This is no small factor in depriving middle and lower class families of the means to finance their children's tertiary education.
The ability of the United States to further equalize educational opportunities can hardly be questioned; the United States still exceeds 19 other advanced countries in this measure, by 13 percent on average. The United States also ranks first among 24 countries in an index of business research and innovation, the adoption of new technology patents, and interaction between business and science. Notwithstanding the current recession, America possesses the wealth and accumulated knowledge to afford the advanced education urged by this valuable and informative work, and should pursue it.

Horst Brand Former Economist with the Bureau of Labor Statistics

## Productivity's role in housing booms and busts

Financial analysts and market observers across the globe have attributed the recent economic downturn to a housing bubble brought on by negligent lending standards and the belief that housing prices would continue to increase indefinitely. But in a recent study, "Productivity Swings and Housing Prices," James A. Kahn of the Federal Reserve Bank of New York indicates that this view is incomplete and that it unjustly exaggerates the role that interest rate changes and credit market irregularities played in the growth and decline of housing prices. Kahn believes that a primary element of the housing boom and bust has been previously ignored by analysts: the role that changing economic fundamentals-specifically, swings in labor productivity, or output per hour of work-play in the movement of housing prices. The author explains that "productivity swings helped determine the price of housing through their effects on income growth and long-term income expec-tations-factors that directly influence what consumers are ready to pay for housing and what mortgage providers are willing to lend." While not discounting the influence that other factors had on housing price movements, Kahn's interpretation is one in which the scope of the effects of the credit condition in the United States is less far-reaching; he considers the credit market irregularities "to have exacerbated the situation caused in large measure by the decline in productivity growth." In other words, it was primarily changing economic fundamentals that led to the financial
distress which resulted in consumers being pummeled by higher interest rates and unable to pay their mortgages; that is, economic fundamentals affected the housing market more than the housing market affected economic fundamentals.
Kahn's data are derived from a model based on productivity data and on estimates of the relationships among income, housing prices, and demand from 1963 through 2008. In the recent housing boom of the late 1990s, there was a period of rebounding productivity growth and a return to a high growth rate, and there also was a noticeably sharp increase in housing prices during the period. The recent downturn in housing prices corresponds to a deceleration in productivity. This trend is observable throughout recent history. During the late 1960s and early 1970s when the productivity rate was trending up, there was a steady upswing in housing prices of 3 percent per year. Then, housing prices declined in the late 1970s as productivity slowed to less than 1.5 percent per year.
How do productivity trends influence housing prices? Productivity growth is the most important determinant of long-term trends in household income. As productivity growth increases, so do income and the prospect of future income. As Kahn explains,"A sustained rise in income will significantly strengthen the current and future demand for housing. The increase in demand will drive up the price of land and hence...the market price of services that owners derive from living in this home." Housing prices are determined by a number of factors, including current income and expectations of future income. If bor-
rowers believe that productivity rates will remain strong, they have reason to suppose their income will continue to increase and are therefore willing to pay higher prices for a house. Similarly, lenders have increased confidence in the ability of the borrowers to pay for the higher expenditure and thus view mortgages as less of a risk.
Further, housing demand is considered relatively inelastic; high prices usually are not enough to dissuade prospective house buyers from purchasing a home. Kahn explains that price-inelastic demand results in home prices growing faster than income during housing booms and declining more rapidly than income during housing busts. Many market analysts interpret these events as merely indicating a housing bubble, but Kahn believes that these price swings "can arise naturally from productivity shifts affecting the demand for housing."
Kahn places a strong emphasis on the importance of the public's perception of productivity. Usually, there is a lag between an actual increase or decrease in productivity and the public recognition of a shift in productivity growth. For example, according to recent estimates productivity growth had begun to slow in 2004, yet there was little public recognition of such a decline until 2007. The recognition of a long-coming slowdown in productivity growth corresponds with a considerable drop in housing prices. The lax lending conditions of the 2000s resulted from an understandablealbeit false-confidence in continued productivity growth. When consumers realized that their faith in continued productivity growth was misplaced, there came a swift decline in economic conditions.

This section of the Review presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

## General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables $1-14,17-21,48$, and 52 . Seasonally adjusted labor force data in tables 1 and 4-9 and seasonally adjusted establishment survey data shown in tables 1,12-14, and 17 are revised in the March 2007 Review. A brief explanation of the seasonal adjustment methodology appears in "Notes on the data."

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average AllItems CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data-such as the "real" earnings shown in table 14 -are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100 . For example, given a current hourly wage rate of $\$ 3$ and a current price index number of 150 , where $1982=100$, the hourly rate expressed in 1982 dollars is $\$ 2(\$ 3 / 150$ $x 100=\$ 2$ ). The $\$ 2$ (or any other resulting
values) are described as "real," "constant," or "1982" dollars.

## Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see BLS Handbook of Methods, Bulletin 2490. Users also may wish to consult Major Programs of the Bureau of Labor Statistics, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau's monthly publication, Employment and Earnings. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

## www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:
www.bls.gov/ces/
Additional information on labor force data for areas below the national level are provided in the BLS annual report, Geographic Profile of Employment and Unemployment.

For a comprehensive discussion of the Employment Cost Index, see Employment Cost Indexes and Levels, 1975-95, BLS Bulletin 2466 . The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: Employee Benefits in Medium and Large Firms; Employee Benefits in Small Private Establishments; and Employee Benefits in State and Local Governments.

More detailed data on consumer and producer prices are published in the monthly periodicals, The CPI Detailed Report and Producer Price Indexes. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the Monthly Labor Revier. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

## www.bls.gov/lpc/

For additional information on international comparisons data, see International Comparisons of Unemployment, Bulletin
1979.

Detailed data on the occupational injury and illness series are published in Occupational Injuries and Illnesses in the United States, by Industry, a BLS annual bulletin.

Finally, the Monthly Labor Review carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

## Comparative Indicators

## (Tables 1-3)

Comparative indicators tables provide an overview and comparison of major blS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on changes in compensation, prices, and productivity are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index
program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

## Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

## Employment and Unemployment Data

(Tables 1; 4-29)

## Household survey data

## Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

## Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12 th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work
because they were on layoff are also counted among the unemployed. The unemployment rate represents the number unemployed as a percent of the civilian labor force.

The civilian labor force consists of all employed or unemployed persons in the civilian noninstitutional population. Persons not in the labor force are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The civilian noninstitutional population comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The civilian labor force participation rate is the proportion of the civilian noninstitutional population that is in the labor force. The employment-population ratio is employment as a percent of the civilian noninstitutional population.

## Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of Employment and Earnings. For a discussion of changes introduced in January 2003, see "Revisions to the Current Population Survey Effective in January 2003" in the February 2003 issue of Employment and Earnings (available on the BLS Web site at www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See "Revision of Seasonally Adjusted Labor Force Series in 2003," in the February 2003 issue of Employment and Earnings (available on the BLS Web site at www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January-June period. The historical season-
ally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July-December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691-6378.

## Establishment survey data

## Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2002 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

## Definitions

An establishment is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private ser-vice-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive, managerial, and supervisory positions. Those
workers mentioned in tables 11-16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. Real earnings are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. Overtime hours represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6month spans are seasonally adjusted, while those for the 12 -month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

## Notes on the data

Establishment survey data are annually adjusted to comprehensive counts of employment (called "benchmarks"). The March 2003 benchmark was introduced in February 2004 with the release of data for January 2004, published in the March 2004 issue of the Review. With the release in June 2003, CES completed a conversion from the Standard Industrial Classification (SIC) system to the North American Industry Classification System (NAICS) and completed the transition from its original quota sample design to a probability-based sample design. The indus-try-coding update included reconstruction of historical estimates in order to preserve
time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of Employment and Earnings and "Recent changes in the national Current Employment Statistics survey," Monthly Labor Review, June 2003, pp. 3-13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of Employment and Earnings, and "Recent changes in the State and Metropolitan Area CES survey," Monthly Labor Review, June 2003, pp. 14-19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4 - versus 5 -week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12-17 in the Review). When all returns have been received, the estimates are revised and published as "final" (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are published as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on
establishment survey data, contact the Division of Current Employment Statistics: (202) 691-6555.

## Unemployment data by State

## Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

## Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691-6392 (table 10) or (202) 691-6559 (table 11).

## Quarterly Census of Employment and Wages

## Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (ucfe) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES202 data, are the most complete enumeration of employment and wage information by industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor
market trends and major industry developments.

## Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of covered workers who worked during, or received pay for, the pay period that included the 12th day of the month. Covered private industry employment includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each ui-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (Ucfe) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An establishment is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the predominant reporting unit or statistical entity for reporting employment and wages
data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly ur report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the ui report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the installation: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into size categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level.It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total wages paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify that wages be reported for, or based on the period during which services are performed
rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as $401(\mathrm{k})$ plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

## Notes on the data

Beginning with the release of data for 2001, publications presenting data from the Covered Employment and Wages program have switched to the 2002 version of the North American Industry Classification System
(NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use
in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because coun-ty-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The NECMA for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1. The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

For additional information on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691-6567.

## Job Openings and Labor Turnover Survey

## Description of the series

Data for the Job Openings and Labor Turnover Survey (JOLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JOLTS program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JOLTS sample design is a random sample drawn from a universe of more than eight million establishments compiled as part of the operations of the Quarterly Census of Em-
ployment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JolTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

## Definitions

Establishments submit job openings in-for-mation for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and job openings, and multiplying that quotient by 100 .

Hires are the total number of additions
to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and parttime, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100 .

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation-quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100 . The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100 .

## Notes on the data

The JOLTS data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supple-mental panels of establishments needed to create NAICS estimates were not completely enrolled until May 2003. The data collected up until those points are from less than a full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled
units were reporting data at that time.
In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JOLTS hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12 th of the month, while the reference period for hires and separations is the calendar month; and (2) payroll employment can vary from month to month simply because part-time and oncall workers may not always work during
the pay period that includes the 12 th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961-5870.

## Compensation and Wage Data

(Tables 1-3; 30-37)
The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

## Employment Cost Index

## Description of the series

The Employment Cost Index (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2002 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are combined to represent one of ten intermediate aggregations, such as professional and related occupations, or one of five higher level aggre-
gations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series-civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current ECI sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

## Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

## Notes on the data

The ECI data in these tables reflect the con-version to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries in the private nonfarm economy was published beginning in 1975. Changes in total compensation cost-wages and salaries and
benefits combined-were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December $2005=100$ ) are available on the Internet: www.bls.gov/ect/

ADDITIONAL InFORMATION on the Employment Cost Index is available at www. bls.gov/ncs/ect/home.htm or by telephone at (202) 691-6199.

## National Compensation Survey Benefit Measures

## Description of the series

NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

## Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having access to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as participating in an insurance or retirement plan if they have paid required contributions and fulfilled any applicable service requirement. Employees in noncontributory plans are counted as participating
regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

## Notes on the data

ADDITIONAL INFORMATION ON THE NCS benefit measures is available at www.bls. gov/ncs/ebs/home.htm or by telephone at (202) 691-6199.

## Work stoppages

## Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

## Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of esti-
mated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

## Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stop-pages data is available at www. bls. gov/cba/home.htm or by telephone at (202) 691-6199.

## Price Data

(Tables 2; 38-46)
Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base pe-riod-December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982-84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 $=100$ for International Price Indexes.

## Consumer Price Indexes

## Description of the series

The Consumer Price Index (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, shortterm workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors'
and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S.city average." Separate estimates for 14 major urban centers are presented in table 39.The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

## Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are meaured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691-7000.

## Producer Price Indexes

## Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the 2002 North American Industry Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

## International Price Indexes

## Description of the series

The International Price Program produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first week of the month. Survey respondents are asked to indicate all discounts, allow-
ances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

## Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000 .

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691-7155.

## Productivity Data

(Tables 2; 47-50)

## Business and major sectors

## Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour, output per unit of labor input, or output per unit of capital input, as well as measures of
multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

## Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. Output per unit of capital services (capital productivity) is the quantity of goods and services produced per unit of capital services input. Multifactor productivity is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). Real compensation per hour is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. Unit nonlabor payments include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures,
land, and inventories-weighted by rental prices for each type of asset.

## Combined units of labor and capital

 inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).
## Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47-50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

FOR ADDITIONAL INFORMATION on this productivity series, contact the Division of Productivity Research: (202) 691-5606.

## Industry productivity measures

## Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

## Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, output indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The labor input series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. Labor compensation includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. Combined inputs include capital, labor, and intermediate purchases. The measure of capital input represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures, land, and inventories. The measure of intermediate purchases is a combination of purchased materials, services, fuels, and electricity.

## Notes on the data

The industry measures are compiled from
data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

## International Comparisons

(Tables 51-53)

## Labor force and unemployment

## Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment approximating U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" Monthly Labor Review, June 2000, pp. 3-20, available on the Internet at www. bls.gov/opub/mlr/2000/06/art1full.pdf.

## Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

## Notes on the data

Foreign country data are adjusted as closely as possible to the U.S. definitions. Primary areas of adjustment address conceptual differences in upper age limits and definitions of employment and unemployment, provided that reliable data are available to make these adjustments. Adjustments are made where applicable to include employed and unemployed persons above upper age limits; some European countries do not include persons older than age 64 in their labor force measures, because a large portion of this population has retired. Adjustments are made to exclude active duty military from employment figures, although a small
number of career military may be included in some European countries. Adjustments are made to exclude unpaid family workers who worked fewer than 15 hours per week from employment figures; U.S. concepts do not include them in employment, whereas most foreign countries include all unpaid family workers regardless of the number of hours worked. Adjustments are made to include full-time students seeking work and available for work as unemployed when they are classified as not in the labor force.

Where possible, lower age limits are based on the age at which compulsory schooling ends in each country, rather than based on the U.S. standard of 16 . Lower age limits have ranged between 13 and 16 over the years covered; currently, the lower age limits are either 15 or 16 in all 10 countries.

Some adjustments for comparability are not made because data are unavailable for adjustment purposes. For example, no adjustments to unemployment are usually made for deviations from U.S. concepts in the treatment of persons waiting to start a new job or passive job seekers. These conceptual differences have little impact on the measures. Furthermore, BLS studies have concluded that no adjustments should be made for persons on layoff who are counted as employed in some countries because of their strong job attachment as evidenced by, for example, payment of salary or the existence of a recall date. In the United States, persons on layoff have weaker job attachment and are classified as unemployed.

The annual labor force measures are obtained from monthly, quarterly, or continuous household surveys and may be calculated as averages of monthly or quarterly data. Quarterly and monthly unemployment rates are based on household surveys. For some countries, they are calculated by applying annual adjustment factors to current published data and, therefore, are less precise indicators of unemployment under U.S. concepts than the annual figures. The labor force measures may have breaks in series over time due to changes in surveys, sources, or estimation methods. Breaks are noted in data tables.

For up-to-date information on adjustments and breaks in series, see the Technical Notes of Comparative Civilian Labor Force Statistics, 10 Countries, on the Internet at www.bls.gov/fls/flscomparelf.htm, and the Notes of Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted, on the Internet at www.bls.gov/fls/flsjec.pdf.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Foreign Labor Statistics: (202) 691-5654 or flshelp@ bls.gov.

## Manufacturing productivity and labor costs

## Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity),output, total hours, compensation per hour, and unit labor costs for the United States, Australia, Canada, Japan, the Republic of Korea, Singapore, Taiwan, and 10 European countries. These measures are trend compari-sons-that is, series that measure changes over time-rather than level comparisons. BLS does not recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures-output, total labor hours, and total compensation. The hours and compensation measures refer to employees (wage and salary earners) in Belgium and Taiwan. For all other economies, the measures refer to all employed persons, including employees, self-employed persons, and unpaid family workers.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). However, the measures for France include parts of mining as well. For the United States and Canada, manufacturing is defined according to the North American Industry Classification System (NAICS 97).

## Definitions

Output. For most economies, the output measures are real value added in manufacturing from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 are indexes of industrial production. The manufacturing value added measures for the United Kingdom are essentially identical to their indexes of industrial production.

For United States, the output measure for the manufacturing sector is a chain-weighted index of real gross product originating (deflated value added) produced by the Bureau of Economic Analysis of the U.S. Department of Commerce. Most of the other economies now also use chain-weighted as opposed to fixed-year weights that are periodically updated.

To preserve the comparability of the U.S. measures with those of other economies, BLS uses gross product originating in manufacturing for the United States. The gross product originating series differs from the manufacturing output series that BLS pub-
lishes in its quarterly news releases on U.S. productivity and costs (and that underlies the measures that appear in tables 48 and 50 in this section). The quarterly measures are on a "sectoral output" basis, rather than a valueadded basis. Sectoral output is gross output less intrasector transactions.

Total hours refer to hours worked in all economies. The measures are developed from statistics of manufacturing employment and average hours. For most other economies, recent years' aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, Singapore, and Sweden, compensation is increased to account for important taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for subsidies.

Labor productivity is defined as real output per hour worked. Although the labor productivity measure presented in this release relates output to the hours worked of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the workforce.

Unit labor costs are defined as the cost of labor input required to produce one unit of output. They are computed as compensation in nominal terms divided by real output. Unit labor costs can also be computed by dividing hourly compensation by output per hour, that is, by labor productivity.

## Notes on the data

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

sion of International Labor Comparison at (202) 691-5654.

## Occupational Injury and IIIness Data

(Tables 54-55)

## Survey of Occupational Injuries and IIInesses

## Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers' job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

## Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both,
because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

## Notes on the data

The definitions of occupational injuries and illnesses are from Recordkeeping Guidelines for Occupational Injuries and Illnesses (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent
full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, Occupational Injuries and Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to bls by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at: www.bls. gov/iif/

## Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety
and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

## Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

## Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 6916175, or the Internet at: www.bls.gov/iif/

[^4][^5]${ }^{5}$ Goods-producing industries include mining, construction, and manufacturing. Serviceproviding industries include all other private sector industries.

NOTE: Beginning in January 2003, household survey data reflect revised population controls. Nonfarm data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC based data.

${ }^{1}$ Seasonally adjusted. "Quarterly average" is percent change from a quarter ago, at an annual rate.
${ }^{2}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard

Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
${ }^{3}$ Excludes Federal and private household workers.
4. Employment status of the population, by sex, age, race, and Hispanic origin, monthly data seasonally adjusted
[Numbers in thousands]

[^7]4. Continued-Employment status of the population, by sex, age, race, and Hispanic origin, monthly data seasonally adjusted [Numbers in thousands]

${ }^{1}$ The population figures are not seasonally adjusted.
${ }^{2}$ Civilian employment as a percent of the civilian noninstitutional population.
${ }^{3}$ Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in J anuary 2003, data reflect revised population controls used in the household survey.

## 5. Selected employment indicators, monthly data seasonally adjusted

[In thousands]

[^8]NOTE: Beginning in January 2003, data reflect revised population controls used in the household survey.
6. Selected unemployment indicators, monthly data seasonally adjusted
[Unemployment rates]

${ }^{1}$ Average weekly wages were calculated using unrounded data.
${ }^{2}$ Percent changes were computed from quarterly employment and pay data adjusted for noneconomic county reclassifications. See Notes on Current Labor Statistics.
${ }^{3}$ Totals for the United States do not include data for Puerto Rico or the

Virgin Islands.
${ }^{4}$ Data do not meet BLS or State agency disclosure standards.
NOTE: Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs. Data are preliminary.
23. Quarterly Census of Employment and Wages: by State, fourth quarter 2008.

${ }^{1}$ Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.
${ }^{2}$ Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.
${ }^{3}$ Consists of legislative, judicial, administrative, and regulatory activities.

Note: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and soc became the official BLS estimates starting in March 2006.

34. Continued-National Compensation Survey: Retirement benefits in private industry by access, participation, and selected series, 2003-2007

${ }^{1}$ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC) System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system.
Only service occupations are considered comparable.
${ }^{2}$ The white-collar and blue-collar occupation series were discontinued effective 2007
${ }^{3}$ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.
Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

${ }^{1}$ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC)
System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.
${ }^{2}$ The white-collar and blue-collar occupation series were discontinued effective 2007.
${ }^{3}$ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.
Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

${ }^{1}$ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:
M-Every month.
1-January, March, May, July, September, and November
2-February, April, June, August, October, and December.
${ }^{2}$ Regions defined as the four Census regions.
${ }^{3}$ Indexes on a December $1996=100$ base
${ }^{4}$ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.
${ }^{5}$ Indexes on a December $1986=100$ base.
${ }^{6}$ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the CPI Detailed

Report: Anchorage, AK; Cincinnatti, OH-KY-IN; Kansas City, MO-KS; Milwaukee-Racine, WI; Minneapolis-St. Paul, MN-WI; Pittsburgh, PA; Port-land-Salem, OR-WA; St Louis, MO-IL; San Diego, CA; Tampa-St. Petersburg-Clearwater, FL.
${ }^{7}$ Indexes on a November $1996=100$ base.
NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.
40. Annual data: Consumer Price Index, U.S. city average, all items and major groups

NOTE: Dash indicates data not available
Quarterly figures for France, Germany, Italy, and the Netherlands are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures. Quarterly figures for Sweden are BLS seasonally adjusted estimates derived from Swedish not seasonally adjusted data. For further qualifications and historical annual data, see the BLS report International comparisons of annual labor force statistics, 10 countries (on the internet at
http://www.bls.gov/fls/flscomparelf.htm). For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the BLS report Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted (on the Internet at http://www.bls.gov/fis/flsjec.pdf). Unemployment rates may differ between the two reports mentioned, because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.
52. Annual data: employment status of the working-age population, approximating U.S. concepts, 10 countries
[Numbers in thousands]

${ }^{1}$ Data for 1989 and subsequent years are based on the Standard Industrial Classification Manual, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985-88, which were based on the Standard Industrial Classification Manual, 1972 Edition, 1977 Supplement.
${ }^{2}$ Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.
${ }^{3}$ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:
$\mathrm{N}=$ number of injuries and illnesses or lost workdays;
$\mathrm{EH}=$ total hours worked by all employees during the calendar year; and $200,000=$ base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).
${ }^{4}$ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.
${ }^{5}$ Excludes farms with fewer than 11 employees since 1976.
NOTE: Dash indicates data not available
